Preface

“Quantum computation is a new conceptual arena
for trying to come to a better understanding of quantum weirdness.”
— N. D. Mermin

There are many books on the subject of quantum information and, in particular, quantum computation. The student or researcher can find the one he/she prefers according to his/her own interests, ranging from the quantum algorithms to the physical implementations of quantum information processing and computation. In the “Suggested bibliography” reported at the end of this preface, the reader can find the list of references I considered to prepare the lectures on quantum computing I have been holding at the Department of Physics of the University of Milan: each book has particular aspects that I appreciated and, therefore, I wanted to communicate to my students. However, when the bibliography is always growing, it is sometimes necessary to provide some useful tools to help the students to follow the lectures and not to get lost into the flow of information coming from the suggested readings.

Motivated also by the requests of my students, I wrote these lecture notes that, year by year, will be corrected (sic!), enhanced and improved with further comments to the old material and by adding new topics concerning quantum computation. Nevertheless, the notes may contain imprecisions and misprints: comments and suggestions are always welcome!

In order to further help the students, at the end of each chapter I put the references to the corresponding chapters of the books or to the research articles that inspired my lectures and should be considered the main resource to begin the advanced study in the field of quantum computation.

I hope that these pages will bring the reader to better understand and appreciate some aspects of our world as described by quantum mechanics.

— Stefano Olivares

Basic concepts of classical logic

Classical information is carried by numerical variables and it is extremely useful to use the binary representation \{0, 1\} in order to encode it. An integer number \( x \) can be written in binary notation as follows:

\[
x \rightarrow x_3 x_2 x_1 x_0,
\]

\[
= x_3 \times 2^3 + x_2 \times 2^2 + x_1 \times 2^1 + x_0 \times 2^0,
\]

where \( x_k \in \{0, 1\}, k = 0, \ldots, 3 \). For instance, \( 1001 \rightarrow 1 \times 2^3 + 0 \times 2^2 + 0 \times 2^1 + 1 \times 2^0 = 9 \).

The amount of information carried by the binary variable is called bit. Each binary variable can take only two values, thus a sequence of \( n \) binary variables can be actually used to name \( N = 2^n \) different numbers. The length of a string tells us the space required to hold the number. We can consider \( \log_2 N = \log_2 2^n = n \) a measure of the information. Note that a single bit carries \( \log_2 2 = 1 \) bit of information.

1.1 Abstract representation of bits

Instead of using the symbols “0” and “1”, we will use the abstract symbols \( |0\rangle \) and \( |1\rangle \), respectively. By using this formalism, the binary string “1001” rewrites as:

\[
1001 \rightarrow |1\rangle |0\rangle |0\rangle |1\rangle,
\]

which represents the state of the four classical bit carrying the information. It is worth noting that, in reality, each symbol \( |x\rangle, x = 0, 1 \), is associated with a physical entity. Therefore, we can identify the numerical value of the classical bit with the bit itself. For the sake of simplicity, we

\[^1\text{We will see later on the mathematical framework of this formalism.}\]
can also use the following notation:  
\[ |1001\rangle \equiv |1\rangle |0\rangle |0\rangle |1\rangle \]

or also write:  
\[ |1001\rangle \equiv |9\rangle_4 \]

where we used the decimal notation “9” to represent the binary value “1001” and the subscript “4” refers to the four bits we used to encode the number (indeed, mathematically, the two binary strings “1001” and “000001001” represent the same digital number “9”, but, physically, the first involves only four bits, the second employs ten bits!!).

It is possible to associate with \( |0\rangle \) and \( |1\rangle \) two column vectors as follows:
\[
|0\rangle \rightarrow \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad \text{and} \quad |1\rangle \rightarrow \begin{pmatrix} 0 \\ 1 \end{pmatrix}.
\]

We clearly see that the two vectors are orthonormal. Now, we note that the symbol \( |1\rangle |0\rangle |0\rangle |1\rangle \) is a short-hand for the tensor product of four single-bit 2-dimensional vectors, namely:
\[
|1\rangle |0\rangle |0\rangle |1\rangle \equiv |1\rangle \otimes |0\rangle \otimes |0\rangle \otimes |1\rangle.
\]

Let’s focus on a 4-dimensional space, with orthonormal basis:
\[
|0\rangle_2 = |00\rangle \rightarrow \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \quad |1\rangle_2 = |01\rangle \rightarrow \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \end{pmatrix}, \quad |2\rangle_2 = |10\rangle \rightarrow \begin{pmatrix} 0 \\ 0 \\ 1 \\ 0 \end{pmatrix}, \quad |3\rangle_2 = |11\rangle \rightarrow \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \end{pmatrix},
\]

where we explicitly evaluated the tensor product\(^2\). In this way it is possible to obtain the \(2^n\)-dimensional column vector representing any of the \(2^n\) possible states of \(n\) bits. If \(x = (x_0, x_1, \ldots, x_{n-1})^T, x_k \in \{0, 1\}, k = 0, \ldots, n-1\), is a column vector associated with the binary representation of an integer \(0 \leq x < 2^n\), then \(x = \sum_{k=0}^{n-1} x_k 2^k\) and we have\(^3\):
\[ |x\rangle_n = |x_{n-1}\rangle \otimes \cdots \otimes |x_0\rangle = |x_{n-1} \cdots x_1 x_0\rangle, \]

i.e., \( |x\rangle_n \) is the tensor product of the single-bit states \( |x_k\rangle \).

### 1.2 Classical logical operations

Any logical or arithmetical operation can be obtained by the composition of three elementary logical operations: “NOT”, “AND” and “OR”. The NOT operation acts on a single bit, while AND and OR are two-bit operations. Their actions are summarized in the truth tables 1.1, 1.2 and 1.3.
1.2 Classical logical operations

| $|x\rangle$ | $|\overline{x}\rangle$ |
|----------|----------|
| $|0\rangle$ | $|1\rangle$ |
| $|1\rangle$ | $|0\rangle$ |

Table 1.1: NOT operation. We used the alternative notation NOT $|x\rangle = |\overline{x}\rangle$.

| $|x\rangle|y\rangle$ | $|x \land y\rangle$ |
|------------------|------------------|
| $|0\rangle|0\rangle$ | $|0\rangle$ |
| $|0\rangle|1\rangle$ | $|0\rangle$ |
| $|1\rangle|0\rangle$ | $|0\rangle$ |
| $|1\rangle|1\rangle$ | $|1\rangle$ |

Table 1.2: AND operation. We used the alternative notation AND $|x\rangle|y\rangle = |x \land y\rangle$.

It is worth noting that the three logical operations introduced above are not independent: given NOT and OR it is possible to obtain the operation AND; analogously, given NOT and AND it is possible to obtain the operation OR. Thus, we can introduce the two universal operators “NOR” (i.e., NOT OR) and “NAND” (i.e., NOT AND):

\[
\text{NOR} |x\rangle|y\rangle \equiv |\overline{x} \lor \overline{y}\rangle = |\overline{x} \land \overline{y}\rangle,
\]

\[
\text{NAND} |x\rangle|y\rangle \equiv |\overline{x} \lor y\rangle = |\overline{x} \lor \overline{y}\rangle.
\]

Another useful operator is the XOR, or exclusive OR operator, which corresponds to the modulo-2 sum. Its action is summarized in table 1.4. Note that $|\overline{x}\rangle = |x \oplus 1\rangle$. As a matter of fact the XOR can be reduced to more elementary operations as:

\[
|x \oplus y\rangle = \big( (x \lor y) \land (x \land y) \big).
\]

1.2.1 Reversible logical operations and permutations

A logical function is reversible if each output arises from a unique input: it is possible to show that a reversible function should be a permutation of the input bit states. The inspection of the tables 1.1–1.4 shows that among the presented operations, only NOT is reversible. Reversibility plays a relevant role in quantum computation, since, as we will see, the general computational process can be modeled with a unitary operation that is indeed reversible.

\[\square \text{ – Exercise 1.1 Prove that NOR and NAND are universal.}\]

---

2The tensor product of the two column vectors $(a_1, \ldots, a_N)^T$ and $(b_1, \ldots, b_M)^T$ is a $NM$-component vector with components indexed by all the $MN$ possible pairs of indices $(v, \mu)$, whose $(v, \mu)^{th}$ component is just the product $a_v b_{\mu}$.

3Note that the binary expansion of the column vector $x = (x_0, x_1, \ldots, x_{n-1})^T$ is $x \rightarrow x_{n-1} \cdots x_1 x_0$. 
1.3 Single-bit reversible operations

The NOT is the only reversible (classical) operation acting on single bits (excluding the identity operator \( \hat{I} \), which is a trivial operation). By using the matrix formalism, we can represent NOT with the \( 2 \times 2 \) matrix:

\[
X \rightarrow \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.
\] (1.1)

Since \( X^2 = \hat{I} \rightarrow \text{1}_2 = \text{diag}(1,1) \) is the \( 2 \times 2 \) identity matrix, it follows that \( X \) is invertible and \( X = X^{-1} \).

It is also instructive to introduce the operators \( \mathbb{N} \), the number operator, and \( \overline{\mathbb{N}} = \hat{I} - \mathbb{N} \):

\[
\mathbb{N}|x\rangle = x|x\rangle, \quad \text{and} \quad \overline{\mathbb{N}}|x\rangle = \pi|x\rangle, \quad x \in \{0, 1\}.
\]

The corresponding matrices are:

\[
\mathbb{N} \rightarrow \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}, \quad \text{and} \quad \overline{\mathbb{N}} \rightarrow \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}.
\]

Classically, \( \mathbb{N} \) and \( \overline{\mathbb{N}} \) are just mathematical operators and do not correspond to a physical operation, e.g. we cannot imagine the meaning of multiplying by 0 the state—not the numerical value—of a bit. . . However, they could be useful from the formal point of view.
\[ - \text{Exercise 1.2} \text{ Verify that } X|x\rangle = |x\rangle. \]

\[ - \text{Exercise 1.3} \text{ Verify that } N^2 = N \text{ and } NN = 0. \]

1.4 Two-bit reversible operations

1.4.1 SWAP

The SWAP operation exchanges the values \(x\) and \(y\) of the two bits \(|x\rangle|y\rangle\):

\[ S|x\rangle|y\rangle = |y\rangle|x\rangle. \]

If we consider the \(n\)-bit state \(|x\rangle_n\), then we can define the operator \(S_{hk}\) which acts on the bits \(h\) and \(k\), namely:

\[ S_{hk}|x\rangle_n = S_{hk}|x_{n-1}\rangle \cdots |x_h\rangle \cdots |x_k\rangle \cdots |x_0\rangle, \]

\[ = |x_{n-1}\rangle \cdots |x_k\rangle \cdots |x_h\rangle \cdots |x_0\rangle. \]

Since \(S_{hk}S_{hk} = \hat{I}\), the SWAP is indeed unitary. It is also possible to represent the SWAP as follows:

\[ S_{hk} = N_h \otimes N_k + N_h \otimes \bar{N}_k + (X_h \otimes X_k) \left(N_h \otimes N_k + \bar{N}_h \otimes N_k\right), \quad (1.2) \]

where \(N_k\), \(\bar{N}_k\) and \(X_k\) have been introduced in section 1.3 and act on the \(k\)-th bits. Sometimes, we will drop the tensor product symbol and we will write:

\[ S_{hk} = N_h N_k + \bar{N}_h \bar{N}_k + X_h X_k \left(N_h \bar{N}_k + \bar{N}_h N_k\right), \quad (1.3) \]

The reader can verify the action of the left-hand-side member of Eq. (1.2) by exploiting the properties of the tensor product and recalling that: (i) given two operators \(A_h\) and \(B_k\), acting on the \(h\)-th and \(k\)-th bits, respectively, one has \(A_h \otimes B_k|x_h\rangle \otimes |x_k\rangle = A_h|x_h\rangle \otimes B_k|x_k\rangle\); (ii) \((A_h \otimes B_k)(C_h \otimes D_h) = (A_h C_h) \otimes (B_k D_h)\).

The matrix representation of \(S_{hk}\) is just a single permutation matrix\(^4\).

1.4.2 Controlled NOT

The controlled NOT, CNOT, is a “workhorse for quantum computation”. This operation acts on a target bit according to the value of a control bit. By definition, \(C_{hk}\) flips the state of the \(k\)-th bit (target state) only if the state of the \(h\)-th bit (control state) is \(|1\rangle\). The action of \(C_{10}\) and \(C_{01}\) is summarized in table 1.5: we can easily see that they act as permutations on the input basis in which only two elements are exchanged.

\(^4\)The explicit form of the permutation matrix associated with \(S_{hk}\) can be obtained starting from the identity matrix and exchanging the \(h\)-th and \(k\)-th columns.
The matrix representations of $C_{01}$ and $C_{10}$ are:

$C_{10} \rightarrow \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}$, $C_{01} \rightarrow \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}$, \hspace{1cm} (1.4)

respectively.

Note that, in general, we can summarize the action of CNOT as follows:

$C_{hk} |x⟩_n = C_{hk} |x⟩_{n-1} \cdots |x_h⟩ \cdots |x_k⟩ \cdots |x_0⟩,$

$= |x_{n-1}⟩ \cdots |x_h⟩ \cdots |x_k \oplus x_h⟩ \cdots |x_0⟩,$

where we used $|x_k \oplus x_h⟩ = |x_k⟩$ if and only if $|x_h⟩ = |1⟩$. It is clear that CNOT acts as a generalized XOR.

\[\square\] \hspace{0.5cm} Exercise 1.4 \hspace{0.5cm} Verify that:

$C_{hk} = \overline{N}_h + N_h X_h,$

where the subscripts refer to the bit affected by the operation.

\[\square\] \hspace{0.5cm} Exercise 1.5 \hspace{0.5cm} Show that the same action of the SWAP can be obtained by the application of three CNOT operations, namely:

$S_{hk} = C_{hk} C_{kh} C_{hk}.$ \hspace{1cm} (1.5)

Now, we introduce the operator:

$Z = \overline{N} - N \rightarrow \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},$

and $XZ = -ZX$. It is straightforward to see that:

$Z|x⟩ = (-1)^x |x⟩, \hspace{0.5cm} x \in \{0, 1\}.$ \hspace{1cm} (1.6)
1.4 Two-bit reversible operations

From a classical point of view the action of $Z$ is meaningless: it multiplies by $-1$ the state $|1\rangle$—note that the state of the bit is multiplied by $-1$ and not its numerical value!

Since, $N = \frac{1}{2}(\mathbb{I} - Z)$ and $\overline{N} = \frac{1}{2}(\mathbb{I} + Z)$ which directly follows from Eq. (1.6), we can write:

$$C_{hk} = \frac{1}{2}(\mathbb{I} + Z_k) + \frac{1}{2}(\mathbb{I} - Z_h)X_h,$$  \hspace{1cm} (1.7a)

$$= \frac{1}{2}(\mathbb{I} + X_h) + \frac{1}{2}Z_h(\mathbb{I} - X_k),$$  \hspace{1cm} (1.7b)

where we dropped the tensor product.

1.4.3 SWAP operator and Pauli matrices

Substituting Eqs. (1.7) into Eq. (1.5), one find the following interesting identity for the SWAP operator:

$$S_{hk} = \frac{1}{2}(\mathbb{I} + Z_hZ_k) + \frac{1}{2}X_hX_k(\mathbb{I} + Z_hZ_k),$$

which may be also written as:

$$S_{hk} = \frac{1}{2}(\mathbb{I} + X_hX_k - Y_hY_k + Z_hZ_k),$$

where:

$$Y_k = Z_kX_k \rightarrow \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

If, however, we introduce the Pauli operators (and the corresponding $2 \times 2$ Pauli matrices):

$$\hat{\sigma}_x \rightarrow \sigma_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \hat{\sigma}_y \rightarrow \sigma_y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \hat{\sigma}_z \rightarrow \sigma_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$  \hspace{1cm} (1.8)

we have:

$$S_{hk} = \frac{1}{2}\left(\mathbb{I} + \sigma_x^{(h)}\sigma_x^{(k)} + \sigma_y^{(h)}\sigma_y^{(k)} + \sigma_z^{(h)}\sigma_z^{(k)}\right),$$

where the superscripts refer to the target bits.

Pauli matrices, together with the identity matrix, form a basis for the $2 \times 2$ matrices and have the following properties:

$$[\hat{\sigma}_x, \hat{\sigma}_y] = \hat{\sigma}_y\hat{\sigma}_x - \hat{\sigma}_x\hat{\sigma}_y = 2i\hat{\sigma}_z,$$

$$[\hat{\sigma}_y, \hat{\sigma}_z] = \hat{\sigma}_z\hat{\sigma}_y - \hat{\sigma}_y\hat{\sigma}_z = 2i\hat{\sigma}_x,$$

$$[\hat{\sigma}_z, \hat{\sigma}_x] = \hat{\sigma}_x\hat{\sigma}_z - \hat{\sigma}_z\hat{\sigma}_x = 2i\hat{\sigma}_y,$$

or, by introducing the totally antisymmetric tensor $\epsilon_{hkl}$, $[\hat{\sigma}_h, \hat{\sigma}_k] = 2i\epsilon_{hkl}\hat{\sigma}_l$.

\(^{5}\)In order to simplify the formalism, we use the following convention:

$$A_h \otimes \mathbb{I}((|x_h\rangle \otimes |x_h\rangle) \equiv A_h(|x_h\rangle \otimes |x_h\rangle),$$

i.e. $A_h \otimes \mathbb{I} \equiv A_h$.

\(^{6}\)It is worth noting that in our formalism if $k \neq h$ we have $A_hB_h = A_k \otimes B_h$, since the two operators refer to different physical entities; the symbol $A_hB_h$ represents the composition of the two operators.
1.4.4 The Hadamard transformation

The Hadamard transformation is defined as:

\[ \mathbf{H} = \frac{1}{\sqrt{2}} (\mathbf{X} + \mathbf{Z}) \rightarrow \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}. \] (1.9)

Though, classically speaking, the action of \( \mathbf{H} \) on \( |x\rangle \) is meaningless, since \( \mathbf{H} \) transforms a single-bit state into a linear combination of states, namely:

\[ \mathbf{H} |x\rangle = \left| 0 \right\rangle + (-1)^x \left| 1 \right\rangle \frac{1}{\sqrt{2}}, \]

or, explicitly:

\[ \mathbf{H} |0\rangle = \frac{\left| 0 \right\rangle + \left| 1 \right\rangle}{\sqrt{2}}, \quad \mathbf{H} |1\rangle = \frac{\left| 0 \right\rangle - \left| 1 \right\rangle}{\sqrt{2}}, \]

this transformation is useful when applied recursively to other operators, as the reader can see from the exercises 1.6 and 1.7.

□ – Exercise 1.6 Show that:

\[ \mathbf{H}X\mathbf{H} = \mathbf{Z} \quad \text{and} \quad \mathbf{H}Z\mathbf{H} = \mathbf{X}, \]

that is, the Hadamard transformation allows to transform \( \mathbf{X} \) into \( \mathbf{Z} \) and vice versa.

□ – Exercise 1.7 Show that:

\[ \mathbf{C}_{hk} = \mathbf{H}_h \mathbf{C}_{kh} \mathbf{H}_k \mathbf{H}_k, \] (1.10)

where the subscripts have the usual meaning – the Hadamard transformation allows to exchange the roles of the target bit and of the control bit of a CNOT, i.e., \( \mathbf{C}_{hk} \rightarrow \mathbf{C}_{kh} \).

Bibliography

Elements of quantum mechanics

In this chapter, we briefly review the structure of quantum mechanics. In particular, the reader can find the postulates of quantum mechanics and the description of the measurement through the positive operator-valued measures (POVMs). The quantum operation will be discussed in chapter 6.

2.1 Dirac notation (in brief)

Throughout this chapter, we use the Dirac braket notation. An $n$-dimensional complex vector (or state) is represented with the symbol $|\psi\rangle_n$, that is called "ket". Given two vectors $|\psi\rangle_n$ and $|\phi\rangle_n$, we use the following symbol for the inner product (we drop the subscript $n$): $\langle \psi | (\langle \phi \rangle) \equiv \langle \psi | \phi \rangle \in \mathbb{C}$. Indeed, $\langle \psi | \phi \rangle$ can be seen as a linear functional associated with the vector $|\psi\rangle$ that takes $|\phi\rangle$ into a complex number. This functional is $(|\psi\rangle)^\dagger = \langle \psi |$, where the symbol $(\cdots)^\dagger$ represents the adjoint operator, and $\langle \psi |$ is called "bra". As usual, the inner product satisfies the following properties:

(i) $\langle \psi | \phi \rangle = \langle \phi | \psi \rangle^*;
(ii) \langle \psi | (\alpha |\phi\rangle + \beta |\gamma\rangle) = \alpha \langle \psi | \phi \rangle + \beta \langle \psi | \gamma \rangle$, $\forall \alpha, \beta \in \mathbb{C};$
(iii) $\langle \psi | \psi \rangle = 0 \iff |\psi\rangle = 0.$

We can expand the $(2^n$-dimensional) vector $|\psi\rangle$ as follows:

$$|\psi\rangle = \sum_{x=0}^{2^n-1} a_x |x\rangle,$$

where $\langle x | y \rangle = \delta_{xy}$ and $\delta_{xy}$ is the Kronecker delta. By using the same association between kets
and vectors introduced in section 1.1, we have:

\[
|\psi\rangle \rightarrow \begin{pmatrix}
\alpha_0 \\
\alpha_1 \\
\vdots \\
\alpha_{2^n-1}
\end{pmatrix}, \quad \text{and} \quad \langle \psi | \rightarrow (\alpha_0^*, \alpha_1^*, \ldots, \alpha_{2^n-1}^*),
\]

where \( \langle x | \psi \rangle = \alpha_x \) and the basis the vectors \(|x\rangle, 0 \leq x < 2^n \), have been introduced in section 1.1. It is now clear that, with this association, the inner product between bras and kets corresponds to the standard inner product between the corresponding vectors.

Let us now consider the linear operator \( \hat{A} \) which acts on a ket \(|\psi\rangle\) leading to a new vector, namely \( \hat{A}|\psi\rangle = |\psi'\rangle \). We have \( (\hat{A}|\psi\rangle)^\dagger = \langle \psi | \hat{A}^\dagger \) and:

\[
\langle \phi | \hat{A} | \psi \rangle = \left( \langle \phi | \hat{A} \right) | \psi \rangle = \langle \phi | (\hat{A} | \psi \rangle) \cdot \left( \hat{A}^\dagger | \phi \rangle \right)^\dagger.
\]

The outer product between \(|\psi\rangle\) and \(|\phi\rangle\) is an operator \(|\psi\rangle \langle \phi |\) whose action on \(|\gamma\rangle\) reads:

\[
|\psi\rangle \langle \phi | (|\gamma\rangle) = |\psi\rangle \langle \phi | |\gamma\rangle \equiv \langle |\gamma\rangle | \psi\rangle.
\]

Furthermore, we have:

\[
|\psi\rangle \langle \phi | \rightarrow \begin{pmatrix}
\alpha_0 \\
\alpha_1 \\
\vdots \\
\alpha_{2^n-1}
\end{pmatrix} \cdot (\beta_0^*, \beta_1^*, \ldots, \beta_{2^n-1}^*) \equiv M,
\]

where \( M \) is a \( 2^n \times 2^n \) matrix with entries \( [M]_{xy} = \alpha_x \beta_y^* \), and we wrote \( |\psi\rangle = \sum_x \alpha_x |x\rangle \) and \( |\phi\rangle = \sum_y \beta_y |y\rangle \).

The operator \( \hat{P}_x = |x\rangle \langle x|, 0 \leq x < 2^n \), is called projector onto the vector \(|x\rangle\) (indeed, one can define a projector \( \hat{P}_\psi = |\psi\rangle \langle \psi |\) onto the state \(|\psi\rangle\)). Since \( \{ |x\rangle \} \) is an orthonormal basis for the \( 2^n \)-dimensional vector space, we have the following completeness relation: \( \sum_x |x\rangle \langle x| = \hat{I} \), that is we have a resolution of the identity operator. The completeness relation may be used to express vectors and operators in a particular orthonormal basis.

\( \square \) \textbf{– Exercise 2.1} Exploiting the completeness relation \( \sum_x |x\rangle \langle x| = \hat{I} \), write the expansion of \(|\psi\rangle\) in the basis \( \{|x\rangle\} \).

\( \square \) \textbf{– Exercise 2.2} Exploiting the completeness relation \( \sum_x |x\rangle \langle x| = \hat{I} \), write the expansion of a linear operator \( \hat{A} \) in the basis \( \{|x\rangle\} \).
2.2 Quantum bits - qubits

We consider the complex vector space generated by the two column vectors associated with the bit states $|0\rangle$ and $|1\rangle$ (that is a 2-dimensional complex Hilbert space). Since the two states form a basis for this space, any linear combination, or superposition:

$$|\psi\rangle = \alpha |0\rangle + \beta |1\rangle \rightarrow \left( \begin{array}{c} \alpha \\ \beta \end{array} \right),$$

(2.1)

where $\alpha, \beta \in \mathbb{C}$, belongs to the space. If $|\alpha|^2 + |\beta|^2 = 1$, i.e., if $|\psi\rangle$ is normalized, we will refer to the state (2.1) as quantum bit or simply qubit. Of course, if $\alpha = 0$ or $\beta = 0$, then $|\psi\rangle = |1\rangle$ or $|\psi\rangle = |0\rangle$, respectively. The basis $\{|0\rangle, |1\rangle\}$ is called computational basis and the information is stored in complex numbers $\alpha$ and $\beta$: it follows that in a single qubit it is possible to encode an infinite amount of information. At least potentially... In fact, in order to extract the information we should perform a measurement on the qubit: as we will see in the next sections, it is a fundamental aspect of Nature that when we observe a system in the superposition state (2.1), we find it either in the state $|0\rangle$ or $|1\rangle$ with a probabilities $p(0) = |\alpha|^2$ and $p(1) = |\beta|^2$, that’s why $|\alpha|^2 + |\beta|^2 = 1$.

Since $|\alpha|^2 + |\beta|^2 = 1$, we can use the following useful parameterization for the amplitudes of the qubit state:

$$\alpha = \cos \frac{\theta}{2}, \quad \beta = e^{i\phi} \sin \frac{\theta}{2},$$

obtaining:

$$|\psi\rangle = \cos \frac{\theta}{2} |0\rangle + e^{i\phi} \sin \frac{\theta}{2} |1\rangle.$$  (2.2)

We will address in the chapters 8 and 9 some examples of the physical realization of qubits.

2.2.1 The Bloch sphere

We can associate with the qubit the following three real numbers:

$$r_x = \sin \theta \cos \phi, \quad r_y = \sin \theta \sin \phi, \quad r_z = \cos \theta,$$

(2.3)

which can be seen as the components of a 3-dimensional vector, i.e.:

$$r = \left( \begin{array}{c} r_x \\ r_y \\ r_z \end{array} \right) = \left( \begin{array}{c} \sin \theta \cos \phi \\ \sin \theta \sin \phi \\ \cos \theta \end{array} \right).$$

The reader may observe that one should write $|\psi\rangle = e^{i\delta} |1\rangle$ or $|\psi\rangle = e^{i\delta} |0\rangle$, but we will see in section 2.3 that a global phase, as $e^{i\delta}$, does not have a physical meaning.

Here we are assuming that the measurement allows to observe as outcomes the state $|0\rangle$ or $|1\rangle$, i.e., the computational basis; of course one may choose a different basis for the measurement, for instance one can also use other computational basis, e.g., $\{|+\rangle, |--\rangle\}$, where $|\pm\rangle = 1/\sqrt{2} (|0\rangle + |1\rangle)$.

More in general one should have $\alpha = e^{i\delta} \cos \frac{\theta}{2}$ and $\beta = e^{i\delta} \sin \frac{\theta}{2}$, but this is equivalent to add a global phase to the state and, thus, we can set $\delta = 0$. 

---

1. The reader may observe that one should write $|\psi\rangle = e^{i\delta} |1\rangle$ or $|\psi\rangle = e^{i\delta} |0\rangle$, but we will see in section 2.3 that a global phase, as $e^{i\delta}$, does not have a physical meaning.

2. Here we are assuming that the measurement allows to observe as outcomes the state $|0\rangle$ or $|1\rangle$, i.e., the computational basis; of course one may choose a different basis for the measurement, for instance one can also use other computational basis, e.g., $\{|+\rangle, |--\rangle\}$, where $|\pm\rangle = 1/\sqrt{2} (|0\rangle + |1\rangle)$.

3. More in general one should have $\alpha = e^{i\delta} \cos \frac{\theta}{2}$ and $\beta = e^{i\delta} \sin \frac{\theta}{2}$, but this is equivalent to add a global phase to the state and, thus, we can set $\delta = 0$. 

Chapter 2: Elements of quantum mechanics

Figure 2.1: The Bloch sphere is represented by the yellow unit sphere, while the red vector represents a pure state, i.e., a state belonging to the surface of the sphere. We also show the two angles $\theta$ (magenta) and $\phi$ (blue) which identify the quantum state.

Furthermore, since $\sqrt{r_x^2 + r_y^2 + r_z^2} = 1$, $r$ represents a point on the surface of the unit sphere, that is the so-called Bloch sphere. In figure 2.1 we show the Bloch sphere and the vectorial representation of a quantum state (the red vector).

In particular we have:

$$|0\rangle = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}, \quad \text{and} \quad |1\rangle = \begin{pmatrix} 0 \\ 0 \\ -1 \end{pmatrix},$$

namely, $|0\rangle$ corresponds to the north pole of the Bloch sphere, whereas $|1\rangle$ to its south pole. The state $|\psi\rangle = 2^{-1/2}(|0\rangle + e^{i\phi}|1\rangle)$, with $\phi \in [0, 2\pi)$, corresponds to equatorial states.

2.2.2 Multiple qubit states

A $n$-qubit state reads:

$$|\Psi\rangle_n = \sum_{x=0}^{2^n-1} a_x |x\rangle_n, \quad \text{with} \quad \sum_{x=0}^{2^n-1} |a_x|^2 = 1,$$

as usual, the subscript $n$ refers to the number of physical entities (qubits) used to encode the information. In particular, the state of two qubits can be written as:

$$|\Psi\rangle_2 = a_{00}|00\rangle + a_{01}|01\rangle + a_{10}|10\rangle + a_{11}|11\rangle,$$

with $|a_{00}|^2 + |a_{10}|^2 + |a_{01}|^2 + |a_{11}|^2 = 1$. In this case, each $|a_{xy}|^2$ corresponds to the joint probability to find the two qubits of the state (2.4) in the state $|xy\rangle$.

2.3 Postulates of quantum mechanics

In this section we introduce quantum mechanics more formally. The postulates of quantum mechanics are a list of prescription to summarize: (1) how to describe the state of a physical
Postulate 1 – States of a quantum system. Each physical system is associated with a complex Hilbert space $\mathcal{H}$ with inner product. The possible states of the physical system correspond to normalized vectors $|\psi\rangle$, $\langle\psi|\phi\rangle = 1$, which contain all the information about the system. For a composite system we have $|\psi\rangle = |\psi\rangle_1 \otimes \ldots \otimes |\psi\rangle_N \in \mathcal{H}$, where $\mathcal{H} = \mathcal{H}_1 \otimes \ldots \otimes \mathcal{H}_N$ is the tensor product of the Hilbert spaces $\mathcal{H}_k$ associated with the $k$-th subsystem. If $|\psi\rangle$ and $|\phi\rangle$ are possible states of a quantum system, then any normalized linear superposition $|\Psi\rangle = \alpha|\psi\rangle + \beta|\phi\rangle$, $\langle\Psi|\Psi\rangle = 1$, is an admissible state of the system (note that, in general, $\langle\psi|\phi\rangle \neq 0$, therefore one may have $\langle\Psi|\Psi\rangle = 1$ but $|\alpha|^2 + |\beta|^2 \neq 1$).

Postulate 2 – Quantum measurements. Observable quantities are described by Hermitian operators $\hat{A}$, that is $\hat{A} = \hat{A}^\dagger$. The operator $\hat{A}$ admits a spectral decomposition $\hat{A} = \sum_a a_x \hat{P}(a_x)$ in terms of the real eigenvalues $a_x$, which are the possible values of the observable, where $\hat{P}(a_x) = |u_x\rangle\langle u_x|$ and $\hat{A}|u_x\rangle = a_x|u_x\rangle$. Note that the orthonormal eigenstates $\{|u_x\rangle\}$ form a basis for the Hilbert space. The probability of obtaining the outcome $a_x$ from the measurement of $\hat{A}$ given the state $|\psi\rangle$ is:

$$p(a_x) = \langle\psi|\hat{P}(a_x)|\psi\rangle = |\langle u_x|\psi\rangle|^2,$$

and the overall expectation value is:

$$\langle \hat{A} \rangle = \langle \psi|\hat{A}|\psi\rangle = \text{Tr} \left[ |\psi\rangle \langle \psi| \hat{A} \right].$$

This is the Born rule, the fundamental recipe to connect the mathematical description of a quantum state $|\psi\rangle$ to the prediction of quantum theory about the results of an experiment. It is now clear that an overall phase has not a physical meaning: the two states $|\psi\rangle$ and $e^{i\theta}|\psi\rangle$, when inserted in Eqs. (2.5) and (2.6), lead to the same results and, thus, represent the same physical state!

Postulate 3 – Dynamics of a quantum system. The dynamical evolution of a physical system from an initial time $t_0$ to a time $t \geq t_0$ is described by a unitary operator $\hat{U}(t,t_0)$, with $\hat{U}(t,t_0)\hat{U}^\dagger(t,t_0) = \hat{U}^\dagger(t,t_0)\hat{U}(t,t_0) = \hat{I}$. If $|\psi_{t_0}\rangle$ is the state of the system at time $t_0$, then at time $t$ we have $|\psi_t\rangle = \hat{U}(t,t_0)|\psi_{t_0}\rangle$. Furthermore, given $\hat{U}(t,t_0)$ there exists a unique Hermitian operator $\hat{H}$ such that (Stone theorem):

$$\hat{U}(t,t_0) = \exp \left[-i\hat{H}(t-t_0)\right],$$

and the form of $\hat{H}$ can be obtained from its identification with the expression for the classical energy of the system, that is the Hamiltonian of the system.
Exercise 2.3 (Two-level system) Given the (quantum) Hamiltonian:

\[
\hat{H} = \hbar [\omega_0 |0\rangle \langle 0| + \omega_1 |1\rangle \langle 1| + \gamma (|1\rangle \langle 0| + |0\rangle \langle 1|)],
\]

where we used the computational basis \{ |0\rangle, |1\rangle \}, find the eigenvalues and the eigenstates of \(\hat{H}\) and calculate:

\[
\hat{U}(t)|1\rangle = \exp \left(-i\hat{H}t/\hbar\right)|1\rangle.
\]

(Hint: express the Hamiltonian in its matrix form...)

2.4 Quantum two-level system: explicit analysis

Since two-level systems are of extreme interest for quantum mechanics and, in particular, for quantum computation, in this section we explicitly solve exercise 2.3 (however, we suggest the reader to study and solve it before reading what follows!).

The \(2 \times 2\) matrix associated with the Hamiltonian of Eq. (2.8) is (without loss of generality we assume the coupling constant \(\gamma \in \mathbb{R}\)):

\[
\hat{H} \rightarrow \begin{pmatrix} E_0 & g \\ g & E_1 \end{pmatrix}
\]

where \(E_k = \hbar \omega_k, k = 0, 1\), and \(g = \hbar \gamma\). The eigenvalues are:

\[
E_{\pm} = \frac{(E_0 + E_1) \pm \sqrt{(\Delta E)^2 + 4g^2}}{2},
\]

with \(\Delta E = E_1 - E_0\), and the corresponding eigenvectors \(|\psi_\pm\rangle\), \(\hat{H}|\psi_\pm\rangle = E_{\pm}|\psi_\pm\rangle\), can be written as:

\[
|\psi_\pm\rangle = c_{0,\pm}|0\rangle + c_{1,\pm}|1\rangle,
\]

whose coefficients \(c_{k,\pm}, k = 0, 1\), satisfy the conditions:

\[
\left(\begin{array}{c} c_{0,\pm} \\ c_{1,\pm} \end{array}\right) = \frac{g}{E_\pm - E_0} \quad \text{and} \quad |c_{0,\pm}|^2 + |c_{1,\pm}|^2 = 1.
\]

After few calculations we find:

\[
c_{0,\pm} = \frac{g}{\sqrt{(E_\pm - E_0)^2 + g^2}} \quad \text{and} \quad c_{1,\pm} = \frac{E_\pm - E_0}{\sqrt{(E_\pm - E_0)^2 + g^2}}.
\]

Since \(\hat{U}(t)|\psi_\pm\rangle = \exp(-i\omega_{\pm}t)|\psi_\pm\rangle\), where \(\hbar \omega_{\pm} = E_{\pm}\), it is straightforward to calculate the time evolution of the computational basis \{ |0\rangle, |1\rangle \}. The time evolution of the generic state \(|\phi_0\rangle = c_+|\psi_+\rangle + c_-|\psi_-\rangle\), \(|c_+|^2 + |c_-|^2 = 1\), reads:

\[
|\phi_t\rangle \equiv \hat{U}(t)|\phi_0\rangle = e^{-i\omega_+t}c_+|\psi_+\rangle + e^{-i\omega_-t}c_-|\psi_-\rangle.
\]
The probability \( p(t) = \langle \phi_0 | \hat{U}(t) | \phi_0 \rangle^2 \) to find the evolved state in the initial state \(| \phi_0 \rangle \) at the time \( t \) is given by:

\[
p(t) = 1 - 4 |c_+|^2 \left( 1 - |c_+|^2 \right) \frac{\sin^2 \left( \frac{\Delta \omega t}{2} \right)}{|c_-|^2},
\]

where we introduced \( \Delta \omega = \omega_+ - \omega_- = \hbar^{-1} \sqrt{(\Delta E)^2 + 4g^2} \) and we used \(|c_+|^2 + |c_-|^2 = 1\). In figure 2.2 we plot \( p(t) \) for two different choices of the coefficient \( c_+ \). The last term of Eq. (2.9) represents the interference of the probability amplitudes, whose visibility is:

\[
V = 4 |c_+|^2 \left( 1 - |c_+|^2 \right).
\]

It is worth noting that the \( V \) reaches its maximum 1 if \(|c_+|^2 = |c_-|^2 = 1/2\) (see the blue dashed line in figure 2.2): the initial state should be a balanced superposition of the eigenstates \(|\psi_\pm\rangle\) of the Hamiltonian (2.8), namely:

\[
|\phi_0\rangle = \frac{|\psi_+\rangle + e^{i\phi}|\psi_-\rangle}{\sqrt{2}},
\]

in this case at times \( t_n \) such that \( \Delta \omega t_n = 2n\pi, \, n \in \mathbb{N} \), one has \( p(t_n) = 0 \) and the evolved system is in the state:

\[
|\phi_{t_n}\rangle \equiv |\phi_0^\perp\rangle = \frac{|\psi_+\rangle - e^{i\phi}|\psi_-\rangle}{\sqrt{2}}
\]

where \( \langle \phi_0^\perp | \phi_0 \rangle = 0 \).

In order to calculate the time evolution of the states \(|0\rangle\) and \(|1\rangle\), we rewrite them as functions of \(|\psi_\pm\rangle\), namely:

\[
|0\rangle = \frac{(E_+ - E_0)\sqrt{(E_- - E_0)^2 + g^2} |\psi_-\rangle - (E_+ - E_0)\sqrt{(E_+ - E_0)^2 + g^2} |\psi_+\rangle}{g(E_+ - E_-)},
\]

\[
|1\rangle = \frac{\sqrt{(E_+ - E_0)^2 + g^2} |\psi_+\rangle + \sqrt{(E_- - E_0)^2 + g^2} |\psi_-\rangle}{g(E_+ - E_-)},
\]
or, in a more compact form:

\[
|0\rangle = a_+ |\psi_+\rangle + a_- |\psi_-\rangle \quad \text{and} \quad |1\rangle = b_+ |\psi_+\rangle + b_- |\psi_-\rangle,
\]

where:

\[
a_\pm = \pm \frac{(E_\pm - E_0) \sqrt{(E_\pm - E_0)^2 + g^2}}{g(E_+ - E_-)} \quad \text{and} \quad b_\pm = \pm \frac{g a_\pm}{E_+ - E_-}.
\]

Exploiting Eq. (2.10) we can easily calculate the corresponding visibilities of the probability amplitudes due to the time evolution, \(V_0 = 4|a_+|^2|a_-|^2\) and \(V_1 = 4|b_+|^2|b_-|^2\), which are the same for both the computational basis states, namely:

\[
V_0 = V_1 = \left[1 + \left(\frac{1}{2} \frac{\Delta E}{g}\right)^2\right]^{-1}, \quad \text{(2.11)}
\]

that are reported in figure 2.3.

\(\square - \text{Exercise 2.4} \quad \text{Prove Eq. (2.11) and plot the probabilities } p_k(t) = |\langle k | \hat{U}(t) | k \rangle|^2, \quad k = 0, 1, \text{as functions of time.}\)

### 2.5 Structure of 1-qubit unitary transformations

Any \(2 \times 2\) complex matrix \(M\) can be written as:

\[
M = r_0 I + r \cdot \sigma,
\]

where \(r = (r_x, r_y, r_z)\), with \(r_k \in \mathbb{C}\), \(\sigma = (\sigma_x, \sigma_y, \sigma_z)^T\), \(\sigma_k\) are the Pauli matrices introduced in Eqs. (1.8), \(k = x, y, z\), and \(r \cdot \sigma = \sum_k r_k \sigma_k\). Here we are interested in unitary transformations, namely, \(M^\dagger M = MM^\dagger = I\), where \(M^\dagger = r_0^* I + r^* \cdot \sigma\). Since \(M\) is unitary, also \(e^{i\theta} M\) is unitary, thus we can assume \(r_0 \in \mathbb{R}\) without loss of generality.

We have:

\[
M^\dagger M = (r_0 I + r^* \cdot \sigma)(r_0^* I + r \cdot \sigma)
\]
that is equivalent to write:

\[ 1 = r_0^2 \mathbb{I} + r_0 (r^* + r) \cdot \sigma + (r^* \cdot \sigma)(r \cdot \sigma). \]

By using the identity \( (a \cdot \sigma)(b \cdot \sigma) = a \cdot b \mathbb{I} + i (a \times b) \cdot \sigma, \forall a, b \in \mathbb{C}^3 \), we obtain the following two conditions:

\[ \begin{align*}
    r_0^2 + r^* \cdot r &= 1, \\
    r_0 (r^* + r) + i (r^* \times r) &= 0.
\end{align*} \tag{2.12a, 2.12b} \]

Since we can write

\[ r^* + r = 2 \text{Re}[r] \quad \text{and} \quad i (r^* \times r) = -2 \text{Im}[r] \times \text{Im}[r], \]

Eq. (2.12b) requires \( \text{Re}[r] \) is parallel to \( \text{Im}[r] \), then \( r = e^{i \phi} \mathbf{v} \) with \( \mathbf{v} \in \mathbb{R}^3 \) and, being \( \mathbf{M} \) unitary, we can simply write \( r = i \mathbf{v} \). The second possibility is \( r_0 \neq 0 \) and, in this case, \( \text{Re}[r] = \text{Re}[r] \times \text{Im}[r] \). Therefore, \( \text{Re}[r] = 0 \) and, again, \( r = i \mathbf{v} \). Summarizing, for an unitary 2 \( \times \) 2 matrix we have:

\[ \mathbf{M} = r_0 \mathbb{I} + i \mathbf{v} \cdot \sigma, \]

where \( \mathbf{v} \in \mathbb{R}^3 \). Furthermore, the condition in Eq. (2.12a) allows us to write:

\[ \mathbf{M} = \cos \gamma \mathbb{I} + i \sin \gamma \mathbf{n} \cdot \sigma, \]

with \( \mathbf{n} = \mathbf{v} / \sqrt{\mathbf{v} \cdot \mathbf{v}} \). Finally, we have the following useful identity:

\[ \exp(i \gamma \mathbf{n} \cdot \sigma) = \cos \gamma \mathbb{I} + i \sin \gamma \mathbf{n} \cdot \sigma. \tag{2.13} \]

- Exercise 2.5 Prove Eq. (2.13) by using the expansion:

\[ \exp(i \gamma \mathbf{n} \cdot \sigma) = \sum_{k=0}^{\infty} \frac{(i \gamma)^k}{k!} (\mathbf{n} \cdot \sigma)^k. \]

2.5.1 Linear transformations and Pauli matrices

The Pauli matrices introduced in Eqs. (1.8) are a basis for 2 \( \times \) 2 matrices. By using the property \( \frac{1}{2} \text{Tr}[\sigma_h \sigma_k] = 2 \delta_{hk} \), we have \( \mathbf{M} = \sum_{k=0}^{3} M_k \sigma_k \), where \( \sigma_0 = \mathbb{I} \) and \( (\sigma_1, \sigma_2, \sigma_3) = (\sigma_x, \sigma_y, \sigma_z) \). Furthermore, by using \( \text{Tr}[\sigma_h \sigma_k] = 2 \delta_{hk} \), or, if separate the three Pauli matrices from the identity:

\[ \mathbf{M} = \frac{1}{2} \left\{ \text{Tr}[\mathbf{M}] \mathbb{I} + \sum_k M_k \sigma_k \right\}, \tag{2.14} \]

that explicitly reads:

\[ \mathbf{M} = \begin{pmatrix} m_{00} & m_{01} \\ m_{10} & m_{11} \end{pmatrix}, \tag{2.15} \]

\[ = \frac{m_{00} + m_{11}}{2} \mathbb{I} + \frac{m_{01} + m_{10}}{2} \sigma_x + i \frac{m_{01} - m_{10}}{2} \sigma_y + \frac{m_{00} - m_{11}}{2} \sigma_z. \tag{2.16} \]
2.6 Quantum states, density operator and density matrix

Let us consider the following statistical ensemble \{ p_x, |\psi_x\rangle \}, in which each state |\psi_k\rangle is prepared with probability p_k. Given the observable \hat{A} and the orthonormal basis \{|\phi_s\rangle\} we have:

\[
\langle \hat{A} \rangle = \sum_x p_x \langle \psi_x | \hat{A} | \psi_x \rangle \\
= \sum_x p_x \langle \psi_x | \left( \sum_s |\phi_s\rangle \langle \phi_s| \right) | \psi_x \rangle \\
= \sum_x \langle \phi_s | \left( \sum_x p_x |\psi_x\rangle \langle \psi_x| \right) \hat{A} | \phi_s \rangle \\
= \sum_s \langle \phi_s | \hat{\varrho} \hat{A} | \phi_s \rangle \equiv \text{Tr}[\hat{\varrho} \hat{A}].
\]

The linear operator \hat{\varrho} is called the density operator. More in general a linear operator:

\[
\hat{q} = \sum_{n,m} q_{n,m} |\phi_n\rangle \langle \phi_m|,
\]

with \( q_{n,m} = \langle \phi_n | \hat{q} | \phi_m \rangle \), is a density operator describing a physical system if \( \hat{q} = \hat{q}^\dagger \), \( \hat{q} \geq 0 \) and \( \text{Tr}[\hat{q}] = 1 \). The matrix \( \varrho \) of the coefficients \( \varrho_{n,m} \) is the density matrix of the physical system. Of course, \( \varrho \) is diagonal if we write it in the basis of its eigenstates.

□ – Example 2.1 The two density operators:

\[
\hat{q}_a = \frac{1}{2} \left( |0\rangle \langle 0| + |0\rangle \langle 1| + |1\rangle \langle 0| + |1\rangle \langle 1| \right), \quad \text{and} \quad \hat{q}_b = |+\rangle \langle +|,
\]

with \( |\pm\rangle = 2^{-1/2} (|0\rangle \pm |1\rangle) \), represent the same statistical ensemble written in different basis. In fact the two orthonormal states \( |\pm\rangle \) are obtained by applying the Hadamard transformation, which is unitary, to the basis \{ |0\rangle, |1\rangle \}.

□ – Exercise 2.6 Write the density matrices of the states in Eqs. (2.17) in the computational basis \{ |0\rangle, |1\rangle \} and in the transformed basis \{ |\pm\rangle \}.

□ – Exercise 2.7 Write the density operator and the density matrix of the state

\[
\hat{q}_c = \frac{1}{2} \left( |+\rangle \langle +| + |\rangle \langle -| \right),
\]

in the computational basis \{ |0\rangle, |1\rangle \} and in the transformed basis \{ |\pm\rangle \}. 

□
2.6 Quantum states, density operator and density matrix

2.6.1 Pure states and statistical mixtures

Note that $\hat{\varrho}_a^2 = \hat{\varrho}_a$ while $\hat{\varrho}_c^2 \neq \hat{\varrho}_c$, where $\hat{\varrho}_a$ and $\hat{\varrho}_c$ are given in Eqs. (2.17) and (2.18), respectively. Therefore we also have $\text{Tr}[\hat{\varrho}_a] = \text{Tr}[\hat{\varrho}_a^2] = 1$ but $\text{Tr}[\hat{\varrho}_c^2] = 1/2 < 1$. Given a density operator $\hat{\varrho}$, in general one has:

$$\mu[\hat{\varrho}] = \text{Tr}[\hat{\varrho}^2] \leq 1,$$

where the real, positive quantity $\mu[\hat{\varrho}]$ is the purity of the state $\hat{\varrho}$. In the case of a $n$-dimensional state we find:

$$\frac{1}{n} \leq \mu[\hat{\varrho}] \leq 1.$$

If $\mu[\hat{\varrho}] < 1$ then the state is a “statistical mixture”, otherwise, i.e., if $\mu[\hat{\varrho}] = 1$, it is “pure”. In fact, in the latter case, we can always write $\hat{\varrho} = |\psi\rangle \langle \psi|$. It is now clear that the state $\hat{\varrho}_c$ of Eq. (2.18) is the maximally mixed state for a qubit, i.e., a 2-dimensional state.

2.6.2 Density matrix of a single qubit

In the case of a single qubit the density matrix $\varrho$ is a $2 \times 2$ matrix and, thus, by means of Eq. (2.14) we can write:

$$\varrho = \frac{1}{2} \left\{ \text{Tr}[\varrho] \mathbb{1} + \text{Tr}[\varrho \sigma_x] \sigma_x + \text{Tr}[\varrho \sigma_y] \sigma_y + \text{Tr}[\varrho \sigma_z] \sigma_z \right\}.$$

A similar relation holds for the density operator:

$$\hat{\varrho} = \frac{1}{2} \left\{ \text{Tr}[\hat{\varrho}] \mathbb{1} + \text{Tr}[\hat{\varrho} \hat{\sigma}_x] \hat{\sigma}_x + \text{Tr}[\hat{\varrho} \hat{\sigma}_y] \hat{\sigma}_y + \text{Tr}[\hat{\varrho} \hat{\sigma}_z] \hat{\sigma}_z \right\}.$$

From now on, we can focus on the matrix representation of the operators, but we have the same result using the operator formalism. Since $\text{Tr}[\hat{\varrho}] = 1$, we find:

$$\varrho = \frac{1}{2} (\mathbb{1} + r \cdot \sigma),$$

where we used the same formalism introduced in section 2.5. Note that, from the physical point of view, the elements of the Bloch vector are the expectations of the Pauli operators, namely, $r_k = \langle \hat{\sigma}_k \rangle = \text{Tr}[\hat{\varrho} \hat{\sigma}_k], k = x, y, z$.

Let us now consider $\varrho^2$, which explicitly reads:

$$\varrho^2 = \frac{1}{4} \left[ \mathbb{1} + 2r \cdot \sigma + (r \cdot \sigma)(r \cdot \sigma) \right].$$

Since $(r \cdot \sigma)(r \cdot \sigma) = r \cdot r \mathbb{1} - i(r \times r) \cdot \sigma = |r|^2 \mathbb{1}$ we have the following expression for the purity:

$$\mu[\varrho] = \frac{1}{2} \left( 1 + |r|^2 \right), \quad (2.19)$$

and, being $\mu[\varrho] \leq 1$, we have the following condition on the Bloch vector $r$:

$$|r| \leq 1, \quad (2.20)$$

which is needed in order to represent a physical state.
2.7 The partial trace

Let $|\psi_{AB}\rangle \in \mathcal{H}_A \otimes \mathcal{H}_B$ and let us consider the measurement of the observable $\hat{A} = \sum_x a_x \hat{P}(a_x)$ on the system $A$. The overall observable measured on the global system $A-B$ writes $\hat{A} \otimes \hat{I}$ and we have the following probability for the outcome $a_x$ (see the Postulate 2 in section 2.3):

$$p(a_x) = \text{Tr}_{AB} [\hat{\rho}_{AB} \hat{A} \otimes \hat{I}], \quad (2.21)$$

with $\hat{\rho}_{AB} = |\psi_{AB}\rangle \langle \psi_{AB}|$. As a matter of fact, the Born rule should be valid also for the single system $A$, thus neglecting system $B$, namely, we can write:

$$p(a_x) = \text{Tr}_{A} [\hat{\rho}_{A} \hat{A}], \quad (2.22)$$

where $\hat{\rho}_{A}$ is the density operator describing the subsystem $A$. It is possible to show that the unique map $\hat{\rho}_{AB} \rightarrow \hat{\rho}_{A}$ that allows to maintain the Born rule at the level of the whole system and subsystem is the partial trace:

$$\hat{\rho}_{A} = \text{Tr}_{B} [\hat{\rho}_{AB}]. \quad (2.23)$$

Note that $\text{Tr}_A[\hat{\rho}_A] = \text{Tr}_{AB}[\hat{\rho}_{AB}] = 1$. In fact, by introducing the orthonormal basis $\{|\phi_K^s\rangle\}$ of the system $K = A, B$, we have:

$$p(a_x) = \text{Tr}_B \text{Tr}_A [\hat{\rho}_{AB} \hat{A} \otimes \hat{I}]$$

$$= \sum_s \langle \phi_s^A | \sum_t \langle \phi_t^B | \hat{\rho}_{AB} \hat{A} \hat{P}(a_x) \hat{I} | \phi_t^B \rangle \rangle \left( \text{Tr}_A[\hat{\rho}_{AB} \hat{A} \otimes \hat{I}] \right)$$

$$= \sum_s \langle \phi_s^A | \sum_t \langle \phi_t^B | \hat{\rho}_{AB} \hat{P}(a_x) \hat{I} | \phi_t^B \rangle \rangle \text{Tr}_B[\hat{\rho}_{AB} \hat{I}]$$

$$= \sum_s \langle \phi_s^A | \sum_t \langle \phi_t^B | \hat{\rho}_{AB} \hat{P}(a_x) | \phi_t^B \rangle \rangle \text{Tr}_B[\hat{\rho}_{AB}]$$

$$= \sum_s \langle \phi_s^A | \hat{\rho}_A \hat{P}(a_x) | \phi_s^A \rangle \rangle$$

$$\equiv \text{Tr}_A [\hat{\rho}_A \hat{P}(a_x)].$$

□ – Exercise 2.8 Given the density operator $\hat{\rho}_{AB}$ describing the state of a bipartite system $A-B$ and the observable $\hat{A} = \sum_x a_x \hat{P}(a_x)$ on the system $A$, show that:

$$\langle \hat{A} \rangle = \text{Tr}_A [\hat{\rho}_A \hat{A}],$$

where $\hat{\rho}_A = \text{Tr}_B[\hat{\rho}_{AB}]$. 

2.7 The partial trace

\[ \hat{\rho}_{AB} \]

\[ \xrightarrow{x, \hat{P}_x} \hat{\rho}_B(x) \quad \text{conditional state} \]

Figure 2.4: Conditional measurement performed on one qubit of a two-qubit state \( \hat{\rho}_{AB} \). See the text for details.

### 2.7.1 Purification of mixed quantum states

Any quantum state \( \hat{\rho}_A \) can be written in the diagonal form choosing its eigenvectors \( \{ |\psi_x^{(A)} \rangle \} \) as the basis for the corresponding Hilbert space \( \mathcal{H}_A \), that is

\[ \hat{\rho}_A = \sum_x \lambda_x |\psi_x^{(A)} \rangle \langle \psi_x^{(A)} |, \]

where \( \lambda_x \geq 0 \) are the eigenvalues. Let us now consider another Hilbert space \( \mathcal{H}_B \) with dimension at least equal to the number of nonzero eigenvalues \( \lambda_x \) and let \( \{ |\theta_x^{(B)} \rangle \} \) a basis of \( \mathcal{H}_B \). We have that the following pure state:

\[ |\Psi_{AB} \rangle = \sum_x \sqrt{\lambda_x} |\psi_x^{(A)} \rangle |\theta_x^{(B)} \rangle, \]

is such that:

\[ \text{Tr}_B[|\Psi_{AB} \rangle \langle \Psi_{AB} |] = \sum_x \lambda_x |\psi_x^{(A)} \rangle \langle \psi_x^{(A)} | = \hat{\rho}_A, \]

that is \( |\Psi_{AB} \rangle \) is a purification of \( \hat{\rho}_A \).

### 2.7.2 Conditional states

The figure 2.4 shows a quantum circuit\(^4\) in which the qubit belonging to the system \( A \) of the input state \( \hat{\rho}_{AB} \) undergoes a projective measurement \( \hat{P}_x \). Given the outcome \( x \) from the measurement, the conditional state of system \( B \) reads:

\[ \hat{\rho}_B(x) = \text{Tr}_A \left[ \hat{P}_x \otimes \mathbb{I} \hat{\rho}_{AB} \hat{P}_x \otimes \mathbb{I} \right] p(x) \]

with \( p(x) = \text{Tr}[\hat{\rho}_{AB} \hat{P}_x \otimes \mathbb{I}] \).

\[ \square \quad \text{Exercise 2.9} \quad \text{Given the following 3-qubit state (the bit order 1-2-3 is from left to right as usual):} \]

\[ |\psi \rangle = \alpha |010 \rangle - \beta |101 \rangle + \gamma |110 \rangle, \]

with \( |\alpha|^2 + |\beta|^2 + |\gamma|^2 = 1 \), write the conditional state of qubits 2 and 3 and the corresponding probability of obtaining it, when one performs a measurement involving only the qubit 1. (Note that the final state should be normalized!)

\(^4\)The representation of quantum evolution and measurement by means of quantum circuits will be discussed in the next chapter.
2.8 Entanglement of two-qubit states

A pure state of two qubits belonging to the Hilbert space $\mathcal{H}_A \otimes \mathcal{H}_B$ which can be written as the tensor product of the two single-qubit states, namely, $|\psi_A\rangle|\phi_B\rangle$ is called factorized or separable state. A state which is not separable is called entangled, as the following state:

$$|\Psi_{AB}\rangle = \frac{|0_A\rangle|0_B\rangle + |1_A\rangle|1_B\rangle}{\sqrt{2}}, \quad (2.24)$$

which cannot be written as a tensor product of the two single-qubit states. In particular the state (2.24) is a maximally entangled state. Entanglement is a key ingredient in many quantum protocols and the characterization of entangled states as well the quantification of this resource is of extreme relevance. A measure $M_E[\hat{\rho}_{AB}]$ of the entanglement of the state $\hat{\rho}_{AB}$ should satisfy the following two conditions:

- $M_E[\hat{\rho}_{AB}] = 0 \iff \hat{\rho}_{AB} = \hat{\rho}_A \otimes \hat{\rho}_B \quad \text{(factorized state)}$;
- given two local unitary operations $\hat{U}_A$ and $\hat{U}_B$ acting the sub-system $A$ and $B$, respectively, $M_E[\hat{U}_A \otimes \hat{U}_B \hat{\rho}_{AB} \hat{U}_A^\dagger \otimes \hat{U}_B^\dagger] = M_E[\hat{\rho}_{AB}]$.

### 2.8.1 Entropy of entanglement

In the presence of pure states, the simplest measure of entanglement is given by the entropy of entanglement $E(\hat{\rho}_{AB}) = S[\hat{\rho}_A] = S[\hat{\rho}_B]$, where

$$S[\hat{\rho}] = -\text{Tr}[\hat{\rho} \log_2 \hat{\rho}]$$

is the von Neumann entropy. In the presence of a pure state $\hat{\rho} = |\psi\rangle\langle\psi|$, one finds $S[\hat{\rho}] = 0$. On the other hand, given a $N$-level system the von Neumann entropy reaches its maximum $S_{\text{max}} = \log_2 N$ for $\hat{\rho} = N^{-1}\hat{I}$, that is the maximally mixed state. Note that, because of the definition of the von Neumann entropy, this measure is independent of the Hilbert space basis and invariant under local unitary operations.

We focus on two two-level systems and start our analysis from the factorized state:

$$|\Psi_{AB}\rangle = \frac{1}{\sqrt{2}} \left( |0_A\rangle + |1_A\rangle \right) \otimes \frac{1}{\sqrt{2}} \left( |0_B\rangle + |1_B\rangle \right) = \frac{1}{2} \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}.$$  \quad (2.25)

Since the state (2.25) a tensor product of two pure states, its entropy of entanglement is null, namely $E(|\Psi_{AB}\rangle) = 0$. Now we consider the two-qubit unitary operation $\text{CPh}(\varphi)$ associated
with the following $4 \times 4$ matrix (we drop the null elements):

$$C\text{Ph}(\varphi) = \begin{pmatrix} 1 & 1 \\ \\ \cos \varphi/2 & -\sin \varphi/2 \\ \\ \sin \varphi/2 & \cos \varphi/2 \end{pmatrix},$$

which corresponds to a controlled phase shift: a phase shift $\varphi$ is applied to the qubit $B$ is the qubit $A$ is the state $|1\rangle$. If $\varphi = \pi$, the action of $C\text{Ph}(\pi)$ is similar to that of the CNOT, up to a phase [see Eq. (1.4)]. We have:

$$|\Phi_{AB}\rangle \equiv C\text{Ph}(\varphi)|\Psi_{AB}\rangle = \frac{1}{2} \begin{pmatrix} 1 \\ -c_- \end{pmatrix},$$

where $c_\pm = \cos \varphi/2 \pm \sin \varphi/2$. The two sub-systems are described by the density matrices:

$$\rho_A = \frac{1}{2} \begin{pmatrix} 1 & 1 \\ \cos \varphi/2 & 1 \end{pmatrix}, \quad \text{and} \quad \rho_B = \frac{1}{2} \begin{pmatrix} 1 - \frac{1}{2} \sin \varphi & \cos \varphi/2 \\ \cos^2 \varphi/2 & 1 + \frac{1}{2} \sin \varphi \end{pmatrix},$$

which both have the following eigenvalues: $\lambda_\pm = \frac{1}{2} \left( 1 \pm \frac{1}{2} \cos \varphi/2 \right)$. The corresponding entropy of entanglement is:

$$E(|\Phi_{AB}\rangle) = -\frac{1}{2} \left( 1 - \frac{1}{2} \cos \varphi/2 \right) \log_2 \left[ \frac{1}{2} \left( 1 - \frac{1}{2} \cos \varphi/2 \right) \right] - \frac{1}{2} \left( 1 + \frac{1}{2} \cos \varphi/2 \right) \log_2 \left[ \frac{1}{2} \left( 1 + \frac{1}{2} \cos \varphi/2 \right) \right],$$

which vanishes for $\varphi = 0, 2\pi$ and reaches the maximum $E(|\Phi_{AB}\rangle) = \log_2 2 = 1$ for $\varphi = \pi$. It is then clear that for $\varphi \neq 0, 2\pi$ the operation $C\text{Ph}(\varphi)$ is an entangling gate.

### 2.8.2 Concurrence

Another measure of entanglement is given by the concurrence. Given the two-qubit pure state:

$$|\psi_{AB}\rangle = \sum_{x,y} \alpha_{xy} |x_A\rangle |y_B\rangle,$$

with $\alpha_{xy} \in \mathbb{C}$, $x, y \in \{0, 1\}$, and $\sum_{x,y} |\alpha_{xy}|^2 = 1$, the concurrence is defined as:

$$C(|\psi_{AB}\rangle) = 2|\alpha_{00}\alpha_{11} - \alpha_{01}\alpha_{10}|.$$  

(2.28)

If $C = 0$, the state is factorized, whereas if $C > 0$, the state is entangled. Since:

$$4|\alpha_{00}\alpha_{11} - \alpha_{01}\alpha_{10}|^2 = 4 \left[ |\alpha_{00}\alpha_{11}|^2 + |\alpha_{01}\alpha_{10}|^2 - \alpha_{00}\alpha_{11}\alpha_{01}\alpha_{10} - \alpha_{00}\alpha_{11}^*\alpha_{01}\alpha_{10}^* \right]$$

$$= 4 \left\{ (|\alpha_{00}|^2 + |\alpha_{01}|^2) (|\alpha_{10}|^2 + |\alpha_{11}|^2) - |\alpha_{00}\alpha_{11} + \alpha_{01}\alpha_{10}|^2 \right\}$$

$$\leq 4 \left( |\alpha_{00}|^2 + |\alpha_{01}|^2 \right) \left[ 1 - |\alpha_{00}|^2 + (|\alpha_{01}|^2) \right] \leq 1,$$
we have $0 \leq C(|\psi_{AB}\rangle) \leq 1$.

The concurrence (2.28) can be written as a function of the purity of the sub-system states. For instance, the density matrix of the sub-system $A$ of the state in Eq. (2.27) reads:

$$\varrho_A = \begin{pmatrix}
|\alpha_{00}|^2 + |\alpha_{01}|^2 & a_{00}\alpha_{01}^* + a_{01}\alpha_{11}^* \\
\alpha_{00}^*a_{01} + \alpha_{01}^*a_{11} & |\alpha_{10}|^2 + |\alpha_{11}|^2
\end{pmatrix},$$

therefore we have $C(|\psi_{AB}\rangle) = 2\sqrt{\det[\varrho_A]}$. Furthermore, using the results of section 2.6.2, we can write $\varrho_A = \frac{1}{2} (1 + r_A \cdot \sigma)$, where $|r_A|^2 = 2\text{Tr}[\varrho_A^2] - 1$, and, thus, we obtain the following expression for the concurrence $C(|\psi_{AB}\rangle) = \sqrt{1 - |r_A|^2}$.

In figure 2.5 we plot the entropy of entanglement and the concurrence of the state (2.26). It is clear that the numerical values of the two entanglement measures are different, but they reach the maximum ($E = C = 1$) in the presence of a maximally entangled state while they both vanish for a factorized state.

Though the entropy of entanglement is a good measure only in the presence of pure two-qubit states, the concurrence can be extended also to mixed states. In this case, given the two-qubit density operator $\hat{\varrho}_{AB}$, the concurrence is given by:

$$C(\hat{\varrho}_{AB}) = \max(0, \lambda_1 - \lambda_2 - \lambda_3 - \lambda_4),$$

where $\lambda_1 \geq \lambda_2 \geq \lambda_3 \geq \lambda_4$ are the eigenvalues of the operator:

$$\hat{R} = \sqrt{\hat{\varrho}_{AB} \hat{\varrho}_{AB}^\dagger} \hat{Q}_{AB},$$

with $\hat{Q}_{AB} = \hat{\sigma}_y \otimes \hat{\sigma}_y \hat{\varrho}_{AB}^\dagger \hat{\sigma}_y \otimes \hat{\sigma}_y$. 

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure2_5.png}
\caption{Plots of the entropy of entanglement $E$ (red solid line) and concurrence $C$ (blue dashed line) of the state $|\Phi_{AB}\rangle$ of Eq. (2.26).}
\end{figure}
2.9 Quantum measurements and POVMs

In the previous sections we have seen that a projective measurement with outcome \( x \) is described by the operators \( \hat{P}_x = \hat{P}_x^2 \geq 0 \), that is \( \hat{P}_x \) is a positive operator. Given the state \( \hat{\psi} \), we have the following expressions for the probability of the outcome \( x \) and the corresponding conditional state \( \hat{\rho}_x \):

\[
p(x) = \text{Tr} \left[ \hat{P}_x \hat{\psi} \hat{P}_x \right] = \text{Tr} \left[ \hat{\psi} \hat{P}_x^2 \right] = \text{Tr} \left[ \hat{\psi} \hat{P}_x \right],
\]

and:

\[
\hat{\rho}_x = \frac{\hat{P}_x \hat{\psi} \hat{P}_x}{p(x)},
\]

respectively.

A generalized measurement, not described by projectors, is a positive operator-valued measure (POVM), i.e., a set of positive operators \( \{ \hat{\Pi}_x \} \), \( \hat{\Pi}_x \geq 0 \), such that \( \sum_x \hat{\Pi}_x = \hat{I} \). In this case we can have \( \hat{\Pi}_x^2 \neq \hat{\Pi}_x \) and the probability of the outcome \( x \) and the corresponding conditional state \( \hat{\rho}_x \) read:

\[
p(x) = \text{Tr} \left[ \hat{\psi} \hat{\Pi}_x \right] = \text{Tr} \left[ \hat{M}_x \hat{\psi} \hat{M}_x^\dagger \right],
\]

where \( \hat{\Pi}_x = \hat{M}_x^\dagger \hat{M}_x \) or \( \hat{M}_x = \sqrt{\hat{\Pi}_x} \), and:

\[
\hat{\rho}_x = \frac{\hat{M}_x \hat{\psi} \hat{M}_x}{p(x)},
\]

respectively.

Bibliography

Chapter 3

Quantum mechanics as computation

IN THIS CHAPTER we introduce the basic framework of quantum computation as an abstract extension of the classical logic. Quantum logic gates and their quantum circuit representations are given. Furthermore, we address the Deutsch, the Deutsch-Josza and the Bernstein-Vazirani algorithms.

3.1 Quantum logic gates

A quantum logic gate transforms an input qubit state as that given in Eq. (2.1) into an output state $|\psi'| = \alpha'|0\rangle + \beta'|1\rangle$. Since the condition $|\alpha'|^2 + |\beta'|^2 = 1$ should be still satisfied, it is possible to show that the action of any quantum logic gate can be represented by a linear unitary transformation associated with the unitary operator $\hat{U}$, namely:

$$|\psi\rangle \rightarrow |\psi'\rangle \equiv \hat{U}|\psi\rangle,$$

(3.1)

where $\hat{U}^\dagger \hat{U} = \hat{U} \hat{U}^\dagger = \mathbb{I}$. Being $\hat{U}$ unitary, not only the normalization of the qubit state is preserved during the transformation, but the operation is intrinsically reversible. In figure 3.1 the unitary transformation (3.1) is schematically represented by means of a quantum circuit: the horizontal lines are “wires” representing the time evolution (from left to right), and they connect the “gates”, represented by means of boxes labeled by the corresponding unitary evolution.

Figure 3.1: Example of a simple quantum circuit involving a single input qubit $|\psi\rangle$ and a unitary (quantum) logic gate $\hat{U}$: $|\psi'\rangle$ correspond to the output state.
3.1.1 Single qubit gates

In chapter 1 we explained that the only reversible classical operation is the NOT operation. In the quantum logic scenario it is represented by the Pauli matrix $\sigma_x$ and the corresponding quantum circuit is sketched in figure 3.2. Note that due to the linearity of the transformation we have:

$$\sigma_x(\alpha|0\rangle + \beta|1\rangle) = \alpha\sigma_x|0\rangle + \beta\sigma_x|1\rangle = \alpha|1\rangle + \beta|0\rangle,$$

as represented in figure 3.2 (b).

In general, a single qubit gate is a linear combination of the Pauli operators. Since any unitary transformation acting on a qubit can be seen as a quantum logic gate, we have infinite single-qubit gates!

**Hadamard transformation** – In particular, the gate associated with the Hadamard transformation $H = \frac{1}{\sqrt{2}}(\sigma_x + \sigma_z)$ defined in Eq. (1.9) not only makes sense (now superpositions of qubit states are allowed!), but it transforms a bit $|x\rangle$ into a superposition and, as we will see, this is a key ingredient of many quantum algorithms. In figure 3.3 we can see the schematic representation of the action of $H$ on a bit and on a qubit, respectively.

**Phase shift gate** – The Pauli operator $\sigma_z$ adds a $\pi$ phase shift between the computational states $|0\rangle$ and $|1\rangle$, since $\sigma_z|x\rangle = e^{-i\pi|x\rangle}$. More in general, the phase shift gate acts as the phase shift operator:

$$e^{-i\phi\sigma_z} = \cos \phi \mathbb{I} - i \sin \phi \sigma_z \rightarrow \begin{pmatrix} e^{-i\phi} & 0 \\ 0 & e^{i\phi} \end{pmatrix} = e^{-i\phi} \begin{pmatrix} 1 & 0 \\ 0 & e^{2i\phi} \end{pmatrix},$$

which adds a relative phase shift $2\phi$ between the computational basis states. Note that in the last equality we can drop the global phase factor $e^{-i\phi}$. 

---

**Figure 3.2:** Quantum circuit for the NOT acting on: (a) the bit $|x\rangle$; (b) the qubit $|\psi\rangle = \alpha|0\rangle + \beta|1\rangle$.

**Figure 3.3:** Quantum circuit for the Hadamard transformation: (a) action of $H$ on a single bit $|x\rangle$; (b) action of $H$ on the qubit $\alpha|0\rangle + \beta|1\rangle$. 

3.1 Quantum logic gates

| x ⟩ \xrightarrow{C_{10}} | x ⟩ \quad \quad \quad | y ⟩ \xrightarrow{σ_z} | y ⊕ x ⟩

\[ C_{10} | x ⟩ \cdot | y ⟩ \equiv C_{10} | x ⟩ \cdot | y ⟩ \quad | y ⊕ x ⟩ \]

Figure 3.4: Two equivalent circuits representing the action of the CNOT gate $C_{10}$. The filled circle is placed on the control qubit wire, while the XOR symbol $⊕$ recall the action of the gate on the target qubit.

$T$ gate or $\frac{\pi}{8}$ gate – This gate, usually referred to as $T$ gate, represents the action of a phase shift gate with $φ = π/8$, namely:

\[ T = \begin{pmatrix} e^{-iπ/8} & 0 \\ 0 & e^{iπ/8} \end{pmatrix} \equiv \begin{pmatrix} 1 & 0 \\ 0 & e^{iπ/4} \end{pmatrix}. \quad (3.2) \]

There are two important gates that can be built starting from the $T$ gate, namely:

\[ T^2 = \begin{pmatrix} 1 & 0 \\ 0 & i \end{pmatrix}, \quad \text{(phase gate)} \]

and:

\[ T^4 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \to \hat{σ}_z. \]

3.1.2 Single qubit gates and Bloch sphere rotations

As a single-qubit pure state can be represented as point on the Bloch sphere (see section 2.2.1), the action of a quantum gate maps point to point and, thus, can be written as the unitary transformation $U = e^{iα R_n(θ)}$, where $R_n(θ) = \exp(iθn · σ)$ is a rotation of $2θ$ around the unit vector $n$. Due to the properties of the rotations, we can decompose $R_n(θ)$ as the combination of rotations around the principal axes $z$ and $y$ axis (or, analogously, $x$ and $y$). Therefore, the unitary transformation $U$ can be written as:

\[ U = e^{iα R_z(β) R_y(γ) R_x(δ)}, \quad (3.3) \]

where the values of the angles $β$, $γ$ and $δ$ depend on $n$ and $θ$.

3.1.3 Two-qubit gates: the CNOT gate

In chapter 1 we have seen that any logical or arithmetical function can be computed from the composition of NOR or NAND two-bit gates, which are thus universal gates. However, these operators are not reversible and, thus, they cannot be represented by means of unitary operators. The irreversibility, in fact, can be seen as a loss of information.
The prototypical multiple qubit gate is the CNOT gate we introduced in section 1.4.2 and whose quantum circuit is shown in figure 3.4 for what concerns the action of $C_{10}$ and in figure 3.5 for $C_{01}$. It is worth noting that CNOT is a reversible operation on two qubits. In the next sections we will see how any multiple qubit gate may be composed from CNOT and single-qubit gates. Figure 3.6 shows the quantum circuit of the SWAP operation and its equivalent realization based on three CNOT gates [see also Eq. (1.5)].

The unitary matrix associated with the CNOT (from now on we consider the first qubit as control) reads:

$$U_{\text{CNOT}} = \begin{pmatrix} 1 & 0 \\ 0 & \sigma_x \end{pmatrix}.$$  

More in general, the unitary matrix $cU$ describing the conditional application of a unitary transformation $U$ to a qubit, namely, $cU|x\rangle|y\rangle = 1 \otimes U^x|x\rangle|y\rangle$ writes:

$$cU = \begin{pmatrix} 1 & 0 \\ 0 & U \end{pmatrix}.$$  

How can we implement the two-qubit gate $cU$ with single-qubit gates and CNOT? We assume that $U$ can be recast in the form (3.3) and introduce the three auxiliary unitary gates:

$$U_A = R_z(\beta) R_y \left( \frac{\gamma}{2} \right), \quad U_B = R_y \left( -\frac{\gamma}{2} \right) R_z \left( \frac{\delta + \beta}{2} \right), \quad \text{and} \quad U_C = R_z \left( \frac{\delta - \beta}{2} \right).$$  

such that $U_A U_B U_C = 1$. Furthermore, since $\sigma_x \sigma_z \sigma_x = -\sigma_z$ and $\sigma_x, \sigma_y \sigma_z = -\sigma_y$, we also have:

$$\sigma_x U_B \sigma_x = R_y \left( \frac{\gamma}{2} \right) R_z \left( \frac{\delta + \beta}{2} \right),$$  

and, thus, $U_A \sigma_x U_B \sigma_x U_C = e^{-i\alpha} U$. 

---

Figure 3.5: Circuit representing the action of the CNOT gate $C_{01}$.

Figure 3.6: Quantum circuit representing the SWAP operation acting on two qubits composed from three CNOT gates.
3.2 Measurement on qubits

As we mentioned, the measurement is a critical point. As sketched in figure 3.8, the result of a measurement on the qubit (2.1) is a single bit $|0\rangle$ or $|1\rangle$ (the double line after the “meter” represents the classical wire carrying one bit of classical information) with a probability given by $|\alpha|^2$ and $|\beta|^2$, respectively. As a matter of fact, during the measurement process performed onto a qubit there is a (huge!) loss of information, which makes the measurement an irreversible process.

3.3 Application and examples

3.3.1 CNOT and No-cloning theorem

One of the peculiar aspect of quantum information is that an unknown quantum state cannot be perfectly cloned. This is a consequence of the linear nature of the operators acting on the quantum states.

In figure 3.9 it is shown how a CNOT gate can be used to clone a (classical) bit $|x\rangle$, $x = 0, 1$. In this case the state of the input bit $|0\rangle$ is converted into the state $|x\rangle$, so that the whole process can be summarized as $|x\rangle|0\rangle \rightarrow |x\rangle|x\rangle$: we end up with two copies of $|x\rangle$. However, if we try to...
3.3.2 Bell states and Bell measurement

As we have seen in section 2.8 the pure state:

\[ |\beta_{00}\rangle = \frac{|00\rangle + |11\rangle}{\sqrt{2}}, \quad (3.4) \]

is entangled since it cannot be written as a tensor product of the two single-qubit states. The state (3.4) is one of the four maximally entangled “Bell states”:

\[ |\beta_{xy}\rangle = \frac{|0y\rangle + (-1)^x|1\rangle}{\sqrt{2}}, \quad (3.5) \]

which can be produced starting from the separable state \(|xy\rangle\) as depicted in figure 3.10. Note that the Bell states are a basis for the two-qubit space.

Indeed, the circuit to generate the Bell states is reversible and its inverse can be used to transform the Bell basis into the usual two-qubit computational basis \(\{|00\rangle, |01\rangle, |10\rangle, |11\rangle\}\), as sketched in figure 3.11. We use both the Bell generation and the Bell measurement in the next section to implement the so-called “quantum teleportation” protocol.

3.3.3 Quantum teleportation

As we pointed out, if we measure in the computational basis \(\{|0\rangle, |1\rangle\}\) a qubit in an unknown quantum state, we will lose any information about it, obtaining as outcome just a classical bit
3.3 Application and examples

Bell measurement

\begin{align*}
(1) & |\psi\rangle \\
(2) & |0\rangle \\
(3) & |0\rangle
\end{align*}

Bell state generation

Figure 3.12: Quantum circuit to perform quantum teleportation.

$|x\rangle$ with a certain probability. However, it is sometimes necessary to transfer the state of a qubit from one part of a quantum computer to another. In this case, the state can be teleported, i.e., the unknown state $|\psi\rangle = \alpha|0\rangle + \beta|1\rangle$ of an input qubit can be reconstructed on a target qubit. The teleportation protocol requires two bits of classical information and a maximally entangled state.

In figure 3.12 we sketched the quantum circuit to implement quantum teleportation. The protocol takes as input the three-qubit state $|\psi\rangle|0\rangle|0\rangle$. The first step is to create an entangled state: following the procedure described in section 3.3.2, we create the Bell state $|\beta00\rangle$ on the qubits 2 and 3 (see figure 3.12): this furnishes the entanglement resource. At this stage the overall three-qubit state reads:

$$|\psi\rangle|00\rangle + |\psi\rangle|11\rangle \sqrt{2}.$$

Then we perform a Bell measurement (see again section 3.3.2) on qubits 1 and 2 by applying the gate $C_{12}$ followed by $H$ acting on qubit 1. After these transformations (but before the measurement!) the three-qubit state writes:

$$\frac{1}{2} \left[ a(|0\rangle + |1\rangle)|00\rangle + a(|0\rangle + |1\rangle)|11\rangle + \beta(|0\rangle - |1\rangle)|10\rangle + \beta(|0\rangle - |1\rangle)|01\rangle \right]$$

that we can rewrite as (we used the properties of the tensor product; note that the order of the qubits is left unchanged):

$$\frac{1}{2} \left[ |00\rangle(a|0\rangle + \beta|1\rangle) + |01\rangle(a|1\rangle + \beta|0\rangle) + |10\rangle(a|0\rangle - \beta|1\rangle) + |11\rangle(a|1\rangle - \beta|0\rangle) \right] \tag{3.6}$$

Equation (3.6) is a superposition of four orthogonal states and can be written in the following compact form:

$$\frac{1}{2} \sum_{M_1=0,1} \sum_{M_2=0,1} |M_1 M_2\rangle \otimes \left[ \hat{\sigma}^{M_2}_x \hat{\sigma}^{M_1}_z (a|0\rangle + \beta|1\rangle) \right], \tag{3.7}$$

where $\hat{\sigma}^{M_2}_x \hat{\sigma}^{M_1}_z$ acts on the qubit 3. It is now clear that a measurement carried out on qubits 1 and 2 with outcomes $|M_1\rangle$ and $|M_2\rangle$, respectively, leave the qubit 3 in the state:

$$\hat{\sigma}^{M_2}_x \hat{\sigma}^{M_1}_z (a|0\rangle + \beta|1\rangle) \equiv \hat{\sigma}^{M_2}_x \hat{\sigma}^{M_1}_z |\psi\rangle. \tag{3.8}$$
Thus, in order to reconstruct the state of the input qubit onto the qubit 3 we should apply to Eq. (3.8) the unitary transformation \( \hat{\sigma}_x^M \hat{\sigma}_z^M \).

It is worth noting that:

- only information is teleported, not matter;
- the input state is lost during the measurement (no-cloning theorem holds);
- no information about the input state is acquired through the measurement (the four outcomes \( |M_1 M_2\rangle \) do not contain any information about \( \alpha \) and \( \beta \) since they occur with the same probability, i.e., 25 %);
- the teleportation protocol is not instantaneous (one should send to the receiver by a classical channels the information about the two output classical bits \( |M_1\rangle \) and \( |M_2\rangle \));
- in order to reconstruct the state of a qubit we need two bits of classical information and the entanglement resource.

### 3.4 The standard computational process

The goal of a computational process is to calculate the values \( f(x) \) of some specified function \( f \) where \( 0 \leq x < 2^k \) is encoded, with an accuracy which increases with \( k \), in the computational-basis state of \( k \) qubits.

Since a quantum computer works with reversible operations, while \( f(x) \) in general isn’t, we should specify \( x \) and \( f(x) \) as an \( n \)-bit and \( m \)-bit integers, respectively. Then we need at least \( n + m \) qubits to perform the task. The set of \( n \) qubits, the input register, encodes \( x \), the set of \( m \)-qubits, the output register, represents the value \( f(x) \). Having separate registers for input and output is standard practice in the classical theory of reversible computation.

In order to perform the calculation of \( f(x) \), we should apply a suitable unitary transformation \( \hat{U}_f \) to our set of \( n + m \) qubits. The standard computational protocol defines the action of \( \hat{U}_f \) on every computational basis state \( |x\rangle_n |y\rangle_m \) of the \( n + m \) qubits making up the input and output registers as follows:

\[
\hat{U}_f |x\rangle_n |y\rangle_m = |x\rangle_n |y \oplus f(x)\rangle_m,
\]

where \( \oplus \) can be seen as a generalized XOR acting on the single bits belonging to the two strings of bits \( y \) and \( f(x) \). Indeed, \( \hat{U}_f |x\rangle_n |0\rangle_m = |x\rangle_n |f(x)\rangle_m \); by initializing the starting output register to \( |0\rangle_m \), after the computation it represents the actual value \( f(x) \).

#### 3.4.1 Realistic computation

The computation of \( f(x) \) may require more than the \( n + m \) qubit introduced in the section 3.4. In figure 3.13 it is sketched a more realistic quantum circuit to carry out the calculation of \( f(x) \),
where an additional register of \( r \) qubits and a unitary transformation \( \hat{W}_f \) acting on \( n + m + r \) qubit is used. As shown in the lower circuit of figure 3.13, the unitary \( \hat{W}_f \) act as follows: the additional \( r \)-qubit state \( |\Psi\rangle_r \) interact with the input register \( |x\rangle_n \) through the unitary operation \( \hat{V}_f \) obtaining the evolution:

\[
\hat{V}_f|\Psi\rangle_r|x\rangle_n = |\Phi\rangle_{n+r-m}|f(x)\rangle_m.
\]

Now, \( m \) controlled-NOT gates perform, bit by bit, the addition modulo 2 with the state of the output register (the control qubits are in the state \( |f(x)\rangle_m \)):

\[
C_m|f(x)\rangle_m|y\rangle_m = |f(x)\rangle_m|y \oplus f(x)\rangle_m.
\]

A final unitary \( \hat{V}_f^\dagger \) is used to obtain the transformation \( \hat{V}_f^\dagger|\Phi\rangle_{n+r-m}|f(x)\rangle_m = |\Psi\rangle_r|x\rangle_n \).

### 3.5 Circuit identities

In figure 3.14 we report useful circuit identities that can be used to better understand the behavior of the quantum circuits described in the following sections. The reader can easily verify them. Here we explicitly consider the identity (f), namely, \( H \otimes HC_{10}H \otimes H \). Since \( C_{10} = \frac{1}{2} (I + \sigma_z) \otimes I + \frac{1}{2} (I - \sigma_z) \otimes \sigma_x \), it is straightforward to verify that:

\[
H \otimes HC_{10}H \otimes H = I \otimes \frac{1}{2} (I + \sigma_z) + \sigma_x \otimes \frac{1}{2} (I - \sigma_z) \equiv C_{01},
\]

where we used the identities (b) and (c) of figure 3.14.

### 3.6 Introduction to quantum algorithms

As we have mentioned, a quantum algorithm involves two registers: the input register \( |x\rangle_n \) and the output register \( |y\rangle_m \). This is due to the reversibility of quantum operations: in general,
a logical operation is not reversible, while the unitary operations indeed are. In this view, a quantum algorithm is similar to a classical reversible computation (of course, in the last case we cannot exploit the quantum features of qubits!).

We recall that the standard computational process that calculates $f(x)$, can be always represented as a suitable unitary operator $\hat{U}_f$ acting on the state $|x\rangle_n|y\rangle_m$, that is $\hat{U}_f|x\rangle_n|y\rangle_m = |x\rangle_n|y \oplus f(x)\rangle_m$.

Given a single qubit $|x\rangle$, $x = 0, 1$, the action of the Hadamard transformation $H$ can be summarized as:

$$H|x\rangle = \frac{|0\rangle + (-1)^x|1\rangle}{\sqrt{2}} = \frac{1}{\sqrt{2}} \sum_{z=0,1} (-1)^{xz}|z\rangle.$$

Therefore, given an $n$-qubit state $|x\rangle_n$, with $0 \leq x < 2^n$ and $x = \sum_{k=0}^{n-1} x_k 2^k$ with $x_k \in \{0,1\}$, we have:

$$H^\otimes n |x\rangle_n = \left( \frac{|0\rangle + (-1)^{x_n-1}|1\rangle}{\sqrt{2}} \right) \otimes \cdots \otimes \left( \frac{|0\rangle + (-1)^{x_0}|1\rangle}{\sqrt{2}} \right)$$

$$= \frac{1}{2^{n/2}} \sum_{z=0}^{2^n-1} (-1)^{x\cdot z}|z\rangle_n,$$

where $x \cdot z = \oplus_{k=0}^{n-1} x_k z_k \pmod{2}$.

It is also useful to note that:

$$\hat{U}_f(\mathbb{I} \otimes H)|x\rangle|1\rangle = |x\rangle \frac{|f(x)\rangle - |1 \oplus f(x)\rangle}{\sqrt{2}} = (-1)^{f(x)}|x\rangle \frac{|0\rangle - |1\rangle}{\sqrt{2}}.$$
3.6 Introduction to quantum algorithms

Figure 3.15: Quantum circuit to solve the Deutsch problem (Deutsch algorithm): if \( f(0) = f(1) \) then \( |y\rangle = |x\rangle \), otherwise \( |y\rangle = |\bar{x}\rangle \), thus measuring the input register after the query we can discriminate between the two possible kind of functions.

We will see that the factor \((-1)^{f(x)}\) is extremely important for quantum algorithms.

3.6.1 Deutsch algorithm

The first pedagogical algorithm we consider has been proposed to solve the so-called Deutsch problem. Given a function \( f : \{0,1\} \rightarrow \{0,1\} \), suppose we are not interested in the particular values \( f(0) \) and \( f(1) \), but rather in a relational information, that is whether \( f(0) = f(1) \) or \( f(0) \neq f(1) \). Form the classical point of view, the only way to solve this problem is to evaluate \( f(x) \) twice. We are going to show that a quantum algorithm can tell us the answer by using just one evaluation of the function. The circuit implementing the algorithm is shown in figure 3.15.

The first step of the algorithm is to apply the Hadamard transformations to the qubit initial states:

\[
H \otimes H |x\rangle|1\rangle = \sum_z \frac{(-1)^z}{\sqrt{2}} |z\rangle \left( \frac{|0\rangle - |1\rangle}{\sqrt{2}} \right)
\]

where \( z = 0,1 \). Now we apply \( \hat{U}_f \):

\[
\hat{U}_f \sum_z \frac{(-1)^z}{\sqrt{2}} |z\rangle \left( \frac{|0\rangle - |1\rangle}{\sqrt{2}} \right) = \sum_z \frac{(-1)^z + f(z)}{\sqrt{2}} |z\rangle \left( \frac{|0\rangle - |1\rangle}{\sqrt{2}} \right).
\]

Finally, we apply again the Hadamard transformations, obtaining the following whole evolution:

\[
(H \otimes H) \hat{U}_f (H \otimes H)|x\rangle|1\rangle = \sum_s c_f(x,s)|s\rangle|1\rangle,
\]

where \( s = 0,1 \), and we introduced the coefficients:

\[
c_f(x,s) = \frac{1}{2} (-1)^{f(0)} \left[ 1 + (-1)^{s+x} (-1)^{f(1) - f(0)} \right].
\]

After the computation the output register has been left unchanged, since it is still in the state \( |1\rangle \), while the input register has undergone the transformation:

\[
|x\rangle \rightarrow \sum_s c_f(x,s)|s\rangle.
\]

It is straightforward to verify that:

- if \( f(1) = f(0) \) then \[ c_f(x,x) = 1 \] and \[ c_f(x,\bar{x}) = 0 \],
- if \( f(1) \neq f(0) \) then \[ c_f(x,x) = 0 \] and \[ c_f(x,\bar{x}) = 1 \],
therefore, if a measurement on the input register gives a result $|x\rangle$, we can conclude that $f(1) = f(0)$, if it leads to $|\overline{x}\rangle$, we have $f(1) \neq f(0)$. This happens after a single query of $\hat{U}_f$. Note that we do not know the actual value of $f(1)$ and $f(0)$: this is a typical quantum tradeoff that scarifies particular information to acquire relational information.

### 3.6.2 Deutsch-Josza algorithm

Now our function is $f : \{0, 1\}^n \rightarrow \{0, 1\}$, that is $f(x) \in \{0, 1\}$ but $0 \leq x < 2^n$. We assume to know that $f$ can only have the following two mutual exclusive properties:

- or $f$ is constant: $f(x) = f(0)$, $\forall x$;
- or $f$ is balanced: $f(x) = 1$, for half of the possible $2^n$ values of $x$, otherwise $f(x) = 0$.

The problem is to decide if $f$ is balanced.

In the best case a deterministic classical computer may solve the problem with just two queries [if $f(0) \neq f(1)$ then $f$ is indeed balanced]. However in the worst case it could happen that the first $2^n/2 = 2^{n-1}$ queries give the same output, then we need one more query to answer the problem: if we have still the same result $f$ is constant, otherwise it is balanced.

A classical randomized algorithm can indeed do better. This algorithm randomly chooses $m \leq 2^{n-1}$ values of $x$, obtaining the set $\{x^{(1)}, \ldots, x^{(m)}\}$, and compare the value $f(x^{(k)})$ with that of $f(x^{(1)})$, $1 < k \leq m$. Given a balanced $f$ and the value $f(x^{(1)})$, the probability that $f(x^{(k)}) = f(x^{(1)})$ is $1/2$. Therefore the probability of failure, that is the probability that $f(x^{(1)}) = f(x^{(k)})$, $\forall k$, is:

$$p_{\text{fail}}(m) = \frac{1}{2} \times \frac{1}{2} \times \ldots \times \frac{1}{2} = \frac{1}{2^{m-1}},$$

where we consider only $m - 1$ values of $x$ because the first one is used as control. We thus obtain that after $m$ queries, the probability of success, i.e., we find that $f$ is balanced, is $p_{\text{succ}}(m) = 1 - p_{\text{fail}}(m)$.

In figure 3.16 we can see the quantum circuit to solve the Deutsch-Josza problem. The input states is the $n + 1$ qubit state $|0\rangle_n |1\rangle$, and, after the application of the Hadamard transformations
and the query of $\hat{U}_f$, we have:

$$\hat{U}_f(H^{\otimes n} \otimes H) |0\rangle_n |1\rangle = \hat{U}_f \sum_{x=0}^{2^n-1} |x\rangle_n \left( \frac{|0\rangle - |1\rangle}{\sqrt{2}} \right) = \frac{1}{2^{n/2}} \sum_{x=0}^{2^n-1} (-1)^{f(x)} |x\rangle_n \left( \frac{|0\rangle - |1\rangle}{\sqrt{2}} \right).$$

Now we should apply the Hadamard transformations:

$$(H^{\otimes n} \otimes H) \hat{U}_f(H^{\otimes n} \otimes H) |0\rangle_n |1\rangle = \frac{1}{2^n} \sum_{x=0}^{2^n-1} \sum_{z=0}^{2^n-1} (-1)^{z \cdot x + f(x)} |z\rangle_n |1\rangle = |\psi\rangle_n |1\rangle,$$

where:

$$|\psi\rangle_n = \sum_{z=0}^{2^n-1} c_f(z) |z\rangle_n,$$  \hspace{1cm} (3.9)

with

$$c_f(z) = \frac{1}{2^n} \sum_{x=0}^{2^n-1} (-1)^{z \cdot x + f(x)}. \hspace{1cm} (3.10)$$

We can focus on:

$$c_f(0) = \frac{1}{2^n} \sum_{x=0}^{2^n-1} (-1)^{f(x)}. \hspace{1cm} (3.11)$$

On the one hand, if $f(x)$ is constant, namely $f(x) = f(0)$, $\forall x$, we have $c_f(0) = (-1)^{f(0)}$, and, since $|\psi\rangle_n$ should be normalized, i.e., $\sum |c_f(z)|^2 = 1$, we obtain $c_f(z) = 0$, $\forall z \neq 0$. On the other hand, if $f(x)$ is balanced we get $c_f(0) = 0$, since the sum in Eq. (3.11) contains $2^n-1$ times the value “$+1$” and $2^n-1$ times the value “$-1$” and, thus, the corresponding state $|\psi\rangle_n$ does not contain $|0\rangle_n$.

Summarizing, the Deutsch-Josza algorithm leads to the following evolution of the $n$-qubit input register:

$$|0\rangle_n \rightarrow \begin{cases} |0\rangle_n & \text{if } f \text{ is constant,} \\
\sum_{z=1}^{2^n-1} c_f(z) |z\rangle_n & \text{if } f \text{ is balanced,} \end{cases}$$

therefore, just after a single call of $U_f$, a measurement of the evolved state of the input register allows us to decide if $f$ is constant (we obtain $|0\rangle_n$) or balanced (in this last case we have $|x\rangle_n$, $x \neq 0$).

It is worth noting that: (i) there is not any known practical application of this kind of algorithm; (ii) the method used to evaluate $f(x)$ is different in the classical and in the quantum case; (iii) the probabilistic algorithms can find the solution of the Deutsch-Josza problem with high probability just after few (random) evaluations of $f(x)$.

\[\square\] \textbf{- Exercise 3.1} Let us consider the Deutsch-Josza problem. Calculate the probability of finding a given $x \neq 0$ in the case of balanced $f$. 
3.6.3 Bernstein-Vazirani algorithm

Let $a$ be an unknown integer number, $0 \leq a < 2^n$ and consider the function:

$$ f(x) = a \cdot x \equiv a_0 x_0 \oplus \cdots \oplus a_{n-1} x_{n-1}. \quad (3.12) $$

The problem is to find the unknown $a$ given a subroutine that evaluates $f(x)$ for an integer $0 \leq x < 2^n$. Classically the only way to solve the problem is to evaluate $f(2^m) \equiv a_m$ for $m = 0, 1, \ldots, n - 1$, which, thus, requires $n$ evaluations of $f(x)$.

Figure 3.17 shows the quantum-circuit representation of the Bernstein-Vazirani problem. The input register encodes the $n$-qubit state $|x\rangle_n = |x_{n-1} \rangle \otimes \cdots \otimes |x_0 \rangle$ while the output register, which is initialized to $|0\rangle$, after the evolution through the unitary operator $\hat{U}_f$ associated with the function defined in Eq. (3.12), becomes $|a \cdot x\rangle$.

The quantum circuit we need to solve the present problem with just one call of $\hat{U}_f$ is the same of the Deutsch-Josza problem (see figure 3.16). Since, now, the action of $f$ is given in Eq. (3.12), the coefficients of the state in Eq. (3.9) read:

$$ c_f(z) = \frac{1}{2^n} 2^{n-1} \sum_{x=0}^{2^n-1} (-1)^x a x = \frac{1}{2^n} 2^{n-1} (-1)^{a x} $$

$$ = \frac{1}{2^n} \sum_{k=0}^{n-1} \prod_{k=0}^{n-1} \sum_{x_k=0,1} (-1)^{a_k x_k} = \frac{1}{2^n} \prod_{k=0}^{n-1} [1 + (-1)^{a_k x_k}]. $$

Form the last equality we conclude that if there exists $k$ such that $z_k \neq a_k$, then $c_f(z) = 0$. Therefore we have:

$$ c_f(z) \rightarrow \begin{cases} 
0 & \text{if } z \neq a, \\
1 & \text{if } z = a,
\end{cases} $$

that is, the evolution of the input register can be summarized as:

$$ |0\rangle_n \rightarrow |a\rangle_n, \quad (3.13) $$

and the measurement of the evolved input register in the computational basis directly gives the unknown value of $a$.

A further investigation of the quantum circuit implementing $\hat{U}_f$ may explain the mechanism underling the Bernstein-Josza algorithm. In particular, in figure 3.18 we illustrate the quantum
The quantum circuit to implement the Bernstein-Vazirani problem for $a = 1101$: if $a_k = 1$ then the bit $k$-th bit acts as control for the NOT operation on to the output register (lowest wire).

Figure 3.19: (Top) Quantum solution of the Bernstein-Vazirani problem. (Bottom) The equivalent quantum circuit to solve the problem for $a = 1101$: we used the identity $C_{hk} = H_hH_kC_{kh}H_hH_k$.

circuit, based on CNOT gates, used to calculate $f(x) = a \cdot x$ in the case of $n = 4$. It is clear that the value $y$ of the output register is flipped only if $a_k$ and $x_k$ are both equal to 1, since the CNOT taking $|x_k\rangle$ as control bit is present in the circuit only if $a_k = 1$. As depicted in figure 3.19 (top), the solution of the problem consists in the application of the Hadamard transformation before and after the unitary $U_f$. But since $C_{hk} = H_hH_kC_{kh}H_hH_k$ (see exercise 1.7 and section 3.5), the resulting circuit is equivalent to the one depicted in figure 3.19 (bottom): it is now straightforward to see that by taking $|0\rangle_n$ and $|1\rangle$ as initial states of the input and output registers, respectively, one has $|0\rangle_n \rightarrow |a\rangle_n$. 

3.7 Classical logic with quantum computers

3.7.1 The Toffoli gate

Any arithmetical operation can be built up on a reversible classical computer out of three-bit controlled-controlled-not (ccNOT) gates called Toffoli gates. The Toffoli gate, represented by the unitary operator $T$, acts on a 3-bit state as follows:

$$T |x⟩|y⟩|z⟩ = |x⟩|y⟩|z ⊕ xy⟩,$$

where $xy$ corresponds to the arithmetical product between the values $x$ and $y$. The action of the Toffoli gate onto the computational basis is summarized in table 3.1. As one can see, $T$ leaves unchanged the third bit, unless the state of the control bits are in the state $|1⟩|1⟩$, in this case the value of the target bit is flipped (see the last two lines of the table). Of course $T$ is reversible and its action on the computational basis is a permutation. The quantum circuit for Toffoli gate is shown in figure 3.20.

As we mentioned in chapter 1, all the logical and, thus, arithmetical operations can be built up out of AND and NOT. By using the Toffoli gate one can calculate the logical AND of two bits, which corresponds to the product of their values, and the NOT, namely:

$$\text{AND} \rightarrow T|x⟩|y⟩|0⟩ = |x⟩|y⟩|xy⟩ \equiv |x⟩|y⟩|x \land y⟩,$$

$$\text{NOT} \rightarrow T|1⟩|1⟩|z⟩ = |1⟩|y⟩|z ⊕ 1⟩ \equiv |1⟩|1⟩|z⟩.$$

Table 3.1: The action of the Toffoli gate.

| $|x⟩|y⟩|z⟩$ | $T|x⟩|y⟩|z⟩$ |
|----------|-----------------|
| $|0⟩|0⟩|0⟩$ | $|0⟩|0⟩|0⟩$ |
| $|0⟩|0⟩|1⟩$ | $|0⟩|0⟩|1⟩$ |
| $|0⟩|1⟩|0⟩$ | $|0⟩|1⟩|0⟩$ |
| $|0⟩|1⟩|1⟩$ | $|0⟩|1⟩|1⟩$ |
| $|1⟩|0⟩|0⟩$ | $|1⟩|0⟩|0⟩$ |
| $|1⟩|0⟩|1⟩$ | $|1⟩|0⟩|1⟩$ |

Figure 3.20: Quantum circuit for the Toffoli gate.

As we mentioned in chapter 1, all the logical and, thus, arithmetical operations can be built up out of AND and NOT. By using the Toffoli gate one can calculate the logical AND of two bits, which corresponds to the product of their values, and the NOT, namely:
Figure 3.21: Quantum circuit acting as a controlled-controlled-\(\hat{U}^2\) gate based on CNOT and controlled-\(\hat{U}\) gates. If we choose \(\hat{U} = \sqrt{\sigma_x}\) (the square root of NOT) we can reproduce the effect of the Toffoli gate.

respectively. We demonstrated the universality of the Toffoli gate. Furthermore, we have:

\[
\begin{align*}
\text{XOR} & \to T |1\rangle |y\rangle |z\rangle = |1\rangle |y\rangle |z \oplus y\rangle, \\
\text{NAND} & \to T |x\rangle |y\rangle |1\rangle = |x\rangle |y\rangle |\overline{x \land y}\rangle.
\end{align*}
\]

We can conclude that it is possible to do any computation reversibly.

We have seen the importance of the Toffoli gate. However, this gate cannot be realized by means of one- or two-bit classical gates. Fortunately, there exist quantum gates! In figure 3.21 is depicted a quantum circuit that acts as a controlled-controlled-\(\hat{U}^2\) gate, where \(\hat{U}\) is a unitary operator \((\hat{U} \hat{U}^\dagger = \hat{U}^\dagger \hat{U} = \hat{I})\), that involves only CNOT and controlled-\(\hat{U}\) gates. The reader can easily verify that the circuit applies the \(\hat{U}^2\) operator to the state \(|z\rangle\) of the output register only if the two-bit input register is \(|x\rangle |y\rangle = |1\rangle |1\rangle\), namely:

\[
|x\rangle |y\rangle |z\rangle \to \hat{I} \otimes \hat{I} \otimes \left[ \hat{U}^2 (\hat{U}^\dagger)^{x \oplus y} \hat{U}^y \right] |x\rangle |y\rangle |z\rangle.
\]

If we now introduce the unitary operator:

\[
\hat{U} = \sqrt{\sigma_x} \to \frac{1}{1+i} \begin{pmatrix} 1 & i \\ i & 1 \end{pmatrix} \quad \text{(square root of NOT)}
\]

such that \(\hat{U}^2 = \sqrt{\sigma_x} \sqrt{\sigma_x} = \sigma_x\), then the ccNOT can be obtained with the quantum circuit of figure 3.21. Note that \(\sqrt{\sigma_x}\) does not exist as a classical gate, but it exists as quantum gate, since:

\[
\sqrt{\sigma_x} |0\rangle = \frac{|0\rangle + i|1\rangle}{1+i}, \quad \sqrt{\sigma_x} |1\rangle = \frac{i|0\rangle + |1\rangle}{1+i}.
\]

### 3.7.2 The Fredkin gate

The Fredkin gate is another three-bit gate which can be used to build a universal set of gates. This gate has one control bit and two targets: when the control bit is 1 the targets are swapped, otherwise they are left unchanged. The action of the Fredkin gate, represented by the unitary operator \(F\), is summarized in table 3.2, whereas we show the corresponding quantum circuit in figure 3.22.
Chapter 3: Quantum mechanics as computation

| $|x\rangle|y\rangle|z\rangle$ | $F|x\rangle|y\rangle|z\rangle$ |
|-----------------------------|-----------------------------|
| $|0\rangle|0\rangle|0\rangle$ | $|0\rangle|0\rangle|0\rangle$ |

| $|1\rangle|0\rangle|0\rangle$ | $|1\rangle|0\rangle|0\rangle$ |
| $|1\rangle|0\rangle|1\rangle$ | $|1\rangle|1\rangle|0\rangle$ |
| $|1\rangle|1\rangle|0\rangle$ | $|1\rangle|0\rangle|1\rangle$ |
| $|1\rangle|1\rangle|1\rangle$ | $|1\rangle|1\rangle|1\rangle$ |

Table 3.2: The action of the Fredkin gate.

![Fredkin gate diagram](image)

Figure 3.22: Quantum circuit for the Fredkin gate.

By suitably setting the input bits it is possible to implement any logical operation. For instance we have:

$$\text{AND} \rightarrow F|x\rangle|y\rangle|0\rangle = |x\rangle|\overline{x} \land y\rangle|x \land y\rangle,$$
$$\text{NOT} \rightarrow F|x\rangle|0\rangle|1\rangle = |x\rangle|x\rangle|\overline{x}\rangle,$$

therefore the Fredkin gate is universal. Note that in the last case we implemented both the COPY and the NOT operations at the same time.

Chapter 4

The Quantum Fourier Transform and the factoring algorithm

In this chapter we introduce the Quantum Fourier Transform (QFT) which is a key ingredient of many quantum protocols. We apply the QFT to the phase estimation problem and we address the factoring algorithm.

4.1 Discrete Fourier transform and QFT

The discrete Fourier transform maps a vector \((x_1, \ldots, x_N)\) of \(N\) complex numbers into a new vector \((y_1, \ldots, y_N)\), where:

\[
y_h = \frac{1}{\sqrt{N}} \sum_{k=1}^{N} \exp\left(\frac{2\pi i}{N} kh\right) x_k.
\]

In a similar way we can define the QFT. Given the \(n\)-qubit state \(|x\rangle_n = \bigotimes_{m=0}^{n-1} |x_m\rangle = |x_{n-1}\rangle|x_{n-2}\rangle\ldots|x_0\rangle\), where \(x\) is an integer number, \(0 \leq x < 2^n\), and \(x_{n-1}x_{n-2}\ldots x_0\) is its binary representation, namely, \(x = \sum_{k=0}^{n-1} x_k 2^k\), with \(x_k \in \{0, 1\}\), we have:

\[
\hat{F}_Q|x\rangle_n = \frac{1}{2^n/2} \sum_{y=0}^{2^n-1} \exp\left(\frac{2\pi i}{2^n} x y\right) |y\rangle_n.
\]  

(4.1)

Since \(|y\rangle_n = \bigotimes_{m=0}^{n-1} |y_m\rangle\) and \(y = \sum_{m=0}^{n-1} y_m 2^m\), we can write (4.1) as:

\[
\hat{F}_Q|x\rangle_n = \frac{1}{2^n/2} \sum_{y_{n-1}=0}^{1} \cdots \sum_{y_0=0}^{1} \bigotimes_{m=0}^{n-1} \exp\left(\frac{2\pi i}{2^n} x y_m 2^{n-m}\right) |y_m\rangle
\]

(4.2)

\[
= \frac{1}{2^n/2} \bigotimes_{m=0}^{n-1} \left[|0\rangle + \exp\left(2\pi i x 2^{n-m}\right) |1\rangle\right] = \bigotimes_{m=0}^{n-1} |\psi_m\rangle,
\]

(4.3)
\[ |x_0\rangle \rightarrow |\psi_0\rangle, \]
\[ |x_1\rangle \rightarrow |\psi_1\rangle, \]
\[ \vdots \]
\[ |x_{n-2}\rangle \rightarrow |\psi_{n-2}\rangle, \]
\[ |x_{n-1}\rangle \rightarrow |\psi_{n-1}\rangle. \]

Figure 4.1: Quantum Fourier transform: the input \( n \)-qubit state \( |x\rangle_n = \bigotimes_{k=0}^{n-1} |x_k\rangle \) is transformed into the output \( n \)-qubit state \( \bigotimes_{k=0}^{n-1} |\psi_k\rangle \). See text for details.

where we defined:
\[ |\psi_m\rangle = \frac{1}{\sqrt{2}} \left[ |0\rangle + \exp \left( 2\pi i \frac{x}{2^{n-m}} \right) |1\rangle \right]. \]

In Fig. 4.1 we show the action of the QFT on the state \( |x\rangle_n \).

In order to find the quantum circuit implementing the QFT, instead of the transformation (4.3) it is better to consider the following one (for the sake of simplicity we use the same symbol \( \hat{F}_Q \) for both the operations):
\[ \hat{F}_Q |x\rangle_n = \frac{1}{2^{n/2}} \bigotimes_{m=1}^{n} \left[ |0\rangle + \exp \left( 2\pi i \frac{x}{2^m} \right) |1\rangle \right] = \bigotimes_{m=1}^{n} |\psi_{n-m}\rangle, \quad (4.4) \]

The subtle difference between (4.3) and (4.4) is that the overall action of the first one can be summarized as:
\[ |x_0\rangle \rightarrow |\psi_0\rangle, \]
\[ |x_1\rangle \rightarrow |\psi_1\rangle, \]
\[ \vdots \]
\[ |x_{n-1}\rangle \rightarrow |\psi_{n-1}\rangle, \]

while in the second case we have:
\[ |x_0\rangle \rightarrow |\psi_{n-1}\rangle, \]
\[ |x_1\rangle \rightarrow |\psi_{n-2}\rangle, \]
\[ \vdots \]
\[ |x_{n-1}\rangle \rightarrow |\psi_0\rangle, \]

or, in a more compact form:
\[ |x_m\rangle \rightarrow |\psi_{n-m-1}\rangle = \frac{1}{\sqrt{2}} \left[ |0\rangle + \exp \left( 2\pi i \frac{x}{2^{m+1}} \right) |1\rangle \right]. \]

Note that we can also write:
\[ \exp \left( 2\pi i \frac{x}{2^{m+1}} \right) = \prod_{k=0}^{n-1} \exp \left( 2\pi i \frac{x_k 2^k}{2^{m+1}} \right), \]
where we used $x = \sum_{k=0}^{n-1} x_k 2^k$. By introducing the function:

$$f_m(z, k) = \begin{cases} 
\exp\left(2\pi i \frac{z}{2m-k+1}\right) & \text{if } 0 \leq k < m, \\
(-1)^k & \text{if } k = m, \\
1 & \text{if } m < k < n,
\end{cases}$$

with $z \in \{0, 1\}$, we have:

$$|x_m\rangle \rightarrow \frac{1}{\sqrt{2}} \left[ |0\rangle + \prod_{k=0}^{m-1} f_m(x_k, k) |1\rangle \right]$$

$$\rightarrow \frac{1}{\sqrt{2}} \left[ |0\rangle + \prod_{k=0}^{m} f_m(x_k, k) |1\rangle \right].$$

If we now define the operator $\hat{R}_h(z)$, such that:

$$\hat{R}_h(z)|0\rangle = |0\rangle, \quad \text{and} \quad \hat{R}_h(z)|1\rangle = \exp\left(2\pi i \frac{z}{2^n}\right) |1\rangle,$$

which corresponds to the $2 \times 2$ matrix:

$$\hat{R}_h(z) \rightarrow \begin{pmatrix} 1 & 0 \\ 0 & \exp\left(2\pi i \frac{z}{2^n}\right) \end{pmatrix},$$

we can write (for $m > 0$):

$$\frac{1}{\sqrt{2}} \left[ |0\rangle + \prod_{k=0}^{m} f_m(x_k, k) |1\rangle \right] = \hat{R}_{m+1}(x_0) \hat{R}_m(x_1) \ldots \hat{R}_2(x_{m-1}) \frac{|0\rangle + (-1)^{x_m}|1\rangle}{\sqrt{2}}$$

$$\hat{H}|x_m\rangle,$$

where $\hat{H}$ is the Hadamard transformation (see Section 1.4.4). In summary:

- if $m = 0$: $|x_0\rangle \rightarrow \hat{H}|x_0\rangle$;
- if $0 < m < n$: $|x_m\rangle \rightarrow \prod_{k=0}^{m-1} \hat{R}_{m-k+1}(x_k) \hat{H}|x_m\rangle$.

As a matter of fact, $\hat{R}_h(0) = \hat{I}$, thus we can see $\hat{R}_h(x_k)$ as a controlled gate, which applies a phase shift to the corresponding qubit only if the control qubit $|x_k\rangle$ assumes the value $x_k = 1$. Therefore, the corresponding quantum circuit involves single-qubit gates (Hadamard transformations) and two-qubit gates [controlled $\hat{R}_h \equiv \hat{R}_h(1)$], as depicted in Fig. 4.2.

In order to reverse the order of the outputs, one should apply at most $n/2$ SWAP gates (recall that three CNOT gates are needed to implement a single SWAP). Besides the SWAPs, the total number of gates involved in Fig. 4.2 is $n + (n-1) + \cdots + 1 = n(n+1)/2 \sim n^2$. Note that the classical Fast Fourier Transform algorithm needs $\sim n 2^n$ gates (since it ignores trivial
4.2 The phase estimation protocol

The phase estimation procedure is a key ingredient for many quantum algorithms. Suppose that \( \hat{U} \) is a unitary operator and \( |u\rangle \) is one of its eigenvectors, such that:

\[
\hat{U}|u\rangle = \exp\left(2\pi i\phi\right)|u\rangle,
\]

where \( \phi \in [0,1) \) is unknown. The binary representation of \( \phi \) is given by \( 0.\phi_1\phi_2\phi_3\ldots \), where \( \phi_k \in \{0,1\} \), and \( \phi = \sum_k \phi_k 2^{-k} \). Since \( \phi \) is an overall phase, we cannot directly retrieve it. However, if we have “black boxes” (the oracles) capable of preparing \( |u\rangle \) and of performing the controlled-\( \hat{U}^{2^{-k}} \) operations, namely \( c\hat{U}^{2^{-k}} \), which use the \( k \)-th qubit as control, we can succeed in the estimation of \( \phi \). Note that since we cannot access \( \hat{U} \) (for this reason it is represented as a “black box”), the phase estimation procedure is not a complete algorithm in its own right.

At first, we assume that \( \phi \) can be exactly specified with \( n \) bits: in this case the estimation procedure allows us to obtain the actual value \( \phi \). The protocol uses two registers: the first one contains \( n \) qubits prepared in the initial state \( |0\rangle_n \); the second one contains many qubits as is necessary to store \( |u\rangle \) (without loss of generality we assume that only one qubit is needed). The first step of the procedure applies \( n \) Hadamard transformations to \( |0\rangle_n \), generating a balanced superposition of all the states \( |x\rangle_n, 0 \leq x < 2^n \). Then we apply controlled-\( \hat{U}^{2^k} \) to \( |u\rangle \) with
4.2 The phase estimation protocol

\[ |0\rangle_n \begin{cases} |0_1\rangle - H & \cdots & \vdots & \cdots & \vdots \\
|0_{n-2}\rangle - H & \cdots & \vdots & \cdots \\
|0_{n-1}\rangle - H & \cdots & \vdots & \cdots \\
|0_n\rangle - H & \cdots & \vdots & \cdots \\
\end{cases} \rightarrow |\Psi(\phi)\rangle_n \]

Figure 4.3: Quantum circuit representing the first step of the phase estimation procedure. The expression of the state \( |\Psi(\phi)\rangle_n \) is given in Eq (4.6).

control qubit corresponding to the \( k \)-th qubit of the first register (see Fig. 4.3).

Since \( c \hat{U}_k^{2^{n-k}} |x_k\rangle|u\rangle = \exp \left( 2\pi i \phi x_k 2^{n-k} \right) |x_k\rangle|u\rangle \), we have (we write only the evolution of the \( k \)-th qubit of the first register and the second register):

\[ c \hat{U}_k^{2^{n-k}} (H \otimes I) |0_k\rangle|u\rangle = \frac{1}{\sqrt{2}} \left[ |0_k\rangle + \exp \left( 2\pi i 2^{n-k} \phi \right) |1_k\rangle \right] |u\rangle \equiv |\psi_k\rangle|u\rangle. \]

Therefore, after the first step of the procedure, the first register evolves as follows (since the second register is left unchanged, we do not write it explicitly):

\[ |0\rangle_n \rightarrow |\psi_n\rangle|\psi_{n-1}\rangle \cdots |\psi_1\rangle \equiv |\Psi\rangle_n. \]

As in the case of Eq. (4.3), we can write:

\[ |\Psi(\phi)\rangle_n = \frac{1}{2^{n/2}} \sum_{x=0}^{2^n-1} \exp \left( 2\pi i \phi x \right) |x\rangle_n. \] (4.6)

Now we apply the inverse of the QFT to \( |\Psi(\phi)\rangle_n \):

\[ \hat{F}^{-1}_Q |\Psi(\phi)\rangle_n = \frac{1}{2^n} \sum_{y=0}^{2^n-1} \sum_{x=0}^{2^n-1} \exp \left[ -2\pi i \frac{xy}{2^n} \right] |y\rangle_n \]
\[ = \frac{1}{2^n} \sum_{y=0}^{2^n-1} \sum_{x=0}^{2^n-1} \exp \left[ -2\pi i x \left( \frac{y - 2^n \phi}{2^n} \right) \right] |y\rangle_n \]
\[ = |2^n \phi\rangle_n \equiv |\phi\rangle_n \] (4.9)

where in Eq. (4.8) we defined the integer number \( \phi \) as:

\[ 2^n \phi = \sum_{m=1}^{n} \varphi_m 2^{-m} = \sum_{k=0}^{u-1} \varphi_{n-k} 2^k \equiv \varphi, \] (4.10)
and we recall that both \(y\) and \(\phi\) are integers less than \(2^n\) [otherwise we don’t have the Kronecker delta, see Eq. (4.11) below]. Finally, since:

\[
|\varphi\rangle_n = |\varphi_n\rangle|\varphi_{n-1}\rangle \cdots |\varphi_1\rangle,
\]

we can retrieve the value of each bit \(\varphi_k\) by measuring the corresponding qubit in the computational basis.

\[\square\]

\textbf{Example 4.1} It this example we consider the \(T\) gate defined in Eq. (3.2). It is straightforward to verify that \(T|1\rangle = e^{2\pi \phi/8}|1\rangle\) with \(\phi = 1/8\) or, in binary notation, \(\phi = 0.01001_2\) (where the subscript \(2\) refers to the chosen basis). The quantum circuit to implement the phase estimation is drawn in figure 4.4. The state of the input register after the inverse of the QFT reads (the proof is left to the reader):

\[
\hat{F}_Q^\dagger \Psi(\phi) = \sum_{y=0}^{2^n-1} |y\rangle \langle y|^{\otimes n}. \tag{4.11}
\]

Since \(2^3 \phi = 1 = 001_2\), we obtain \(\hat{F}_Q^\dagger \Psi = |2^3 \phi\rangle_3 = |01\rangle|02\rangle|13\rangle\).

If the actual value of the phase, say \(\phi^*\), cannot be exactly written with an \(n\)-bit expression, then the estimation does not give its actual value, but just an approximation. In fact, in this case \(2^n \phi^*\) is not an integer and Eq. (4.8) becomes:

\[
\begin{align*}
\hat{F}_Q^\dagger \Psi(\phi)_{\text{n}} &= \sum_{y=0}^{2^n-1} \frac{1}{2^n} \left[ 1 - \exp \left( -2\pi i \left( y - 2^n \phi^* \right) \right) \right] |y\rangle_n, \\
&= \sum_{y=0}^{2^n-1} f_y(\phi^*; n) |y\rangle_n, \tag{4.11}
\end{align*}
\]

that is a superposition of all the possible outcomes \(|y\rangle_n\), each with probability:

\[
p(y) = |f_y(\phi^*; n)|^2 = \frac{1}{2^n} \frac{1 - \cos \left[ 2\pi \left( y - 2^n \phi^* \right) \right]}{1 - \cos \left[ 2\pi \left( y - 2^n \phi^* \right) 2^{-n} \right]}. \tag{4.12}
\]
4.2 The phase estimation protocol

The phase estimation protocol is a quantum algorithm that estimates the unknown phase \( \phi \) of a unitary operator. Given a Hamiltonian \( H \), the algorithm prepares a state in the form of a quantum wave packet, which is then evolved under \( e^{iHt} \). The phase \( \phi \) is estimated by measuring the state in the computational basis.

**Figure 4.5:** Plot of \( p(y) \) given in Eq. (4.12) for the estimation of the phase \( \phi^* = 0.6875 \), that has the exact binary expansion 0.1011₂. We used a different number \( n \) of qubits for the input register, from left to right: \( n = 4, 3 \) and \( 2 \).

**Figure 4.6:** Plot of \( p(y) \) given in Eq. (4.12) for the estimation of the phase \( \phi^* = 0.2 \), that does not have an exact binary expansion (0.00110011 . . .), using an increasing number \( n \) of qubits for the input register, from left to right \( n = 2, 4 \) and \( 8 \).

The reader can check that \( p(y) \geq 0 \) and \( \sum_{y=0}^{2^n-1} p(y) = 1 \). In the figures 4.5 and 4.6 we plot the outcome probability \( p(y) \) for two values of the unknown phase and a different number \( n \) of qubits of the input register.

Among the possible outcomes of the measurement there will be a particular integer \( \phi^{(b)} \), \( 0 \leq \phi^{(b)} < 2^n \), such that \( \phi^{(b)} = 2^{-n}\phi^* \), is the best \( n \)-bit approximation of the actual value \( \phi^* \). One of the interesting features of the phase-estimation procedure we described, is that, given a positive integer \( t \) representing the tolerance to error, the probability to obtain as outcome of the measurement an integer \( \phi \) corresponding to the phase \( \phi = 2^{-n}\phi^* \), such that \( |\phi - \phi^{(b)}| > t \), decreases as \( t \) increases. It is possible to show that this probability is given by:

\[
p \left( |\phi - \phi^{(b)}| > t \right) \leq \frac{1}{2(t-1)}.
\]

and, thus, the probability to get an estimation of \( \phi \) within the tolerance \( t \), the is the success probability, reads:

\[
p \left( |\phi - \phi^{(b)}| \leq t \right) > 1 - \frac{1}{2(t-1)}.
\]

Furthermore, the higher is the number of qubits \( n \), the better is the approximation. For instance,
suppose we want to approximate $\phi$ to an accuracy $2^{-q}$, $0 < q < n$, namely:

$$\left| \phi - \phi^{(b)} \right| < 2^{-q},$$

or, equivalently, multiplying both sides by $2^n$:

$$\left| \phi - \phi^{(b)} \right| \leq t = 2^{n-q} - 1,$$

(note that $2^{n-q} - 1$ corresponds to the maximum integer which can be encoded using only $n - q$ bits). If we require $p(|\phi - \phi^{(b)}| \leq t) = 1 - \epsilon$, for a given $\epsilon > 0$, then the number $n$ of required qubits for the first register should be at least:

$$n = q + \left\lceil \log_2 \left( \frac{2}{2\epsilon} \right) \right\rceil,$$

(4.13)

where $[z]$ is the ceiling function, which represents the smallest integer not less than $z \in \mathbb{R}$.

### 4.3 The factoring algorithm (Shor algorithm)

The aim of a factoring algorithm is to find the nontrivial factors of an integer $N$. In this section we show that the factoring problem turns out to be equivalent to the so-called order-finding problem we just studied, in the sense that a fast algorithm for order finding can easily be turned into a fast algorithm for factoring. The algorithm is essentially based on two theorems and it is useful to recall the following concepts. Given three integer numbers $a$, $b$ and $N$, we have that:

$$a = b \ (\text{mod} \ N) \Rightarrow \exists q \in \mathbb{Z} \text{ such that } a - b = q N.$$

Suppose, now, to have two integers, $x$ and $N$, $x < N$, with no common factors. The order of $x$ modulo $N$ is defined to be the least positive integer $r$ such that $x^r \ (\text{mod} \ N) = 1$.

□ – **Example 4.2** Given $x = 5$ and $N = 21$, we have:

- $5\ (\text{mod} \ 21) = 5$, $5^4 \ (\text{mod} \ 21) = 16$, $5^2 \ (\text{mod} \ 21) = 4$, $5^3 \ (\text{mod} \ 21) = 17$, $5^3 \ (\text{mod} \ 21) = 20$, $5^6 \ (\text{mod} \ 21) = 1$.

Therefore the order of 5 modulo 21 is $r = 6$.

□ – **Example 4.3** Given $x = 3$ and $N = 10$, we have:

- $3\ (\text{mod} \ 10) = 3$, $3^3 \ (\text{mod} \ 10) = 7$, $3^2 \ (\text{mod} \ 10) = 9$, $3^4 \ (\text{mod} \ 10) = 1$.

Therefore the order of 3 modulo 10 is $r = 4$. 

4.3 The factoring algorithm (Shor algorithm)

□ – Exercise 4.1 Prove that given the integers \(x, y\) and \(N\), one has:

\[
[x \pmod N] [y \pmod N] = [xy \pmod N].
\]  

(4.14)

Note that if \(r\) is the order of \(x\) modulo \(N\), then \(x^{(r+s)} \pmod N = x^s \pmod N\), with 0 \(\leq s < r\).

We can now state the two theorems that are at the basis of the factoring algorithm:

Theorem 4.1 Suppose \(N\) is an \(L\)-bit composite number, and \(x\) is a non-trivial solution to the equation \(x^2 = 1 \pmod N\) in the range \(1 \leq x \leq N\), that is, \(x \neq \pm 1 \pmod N\). Then at least one of \(\gcd(x - 1, N)\) and \(\gcd(x + 1, N)\) is a non-trivial factor of \(N\) that can be computed using \(O(L^3)\) operations.

Note that if \(x \in [1, N]\), then we have:

\(x \neq 1 \pmod N \Rightarrow x \neq 1\), and \(x \neq -1 \pmod N \Rightarrow x \neq N - 1\).

The problem is thus reduced to find a non-trivial solution \(x\) to \(x^2 = 1 \pmod N\). This second theorem can help us.

Theorem 4.2 Suppose \(N = p_1^{a_1} \cdots p_m^{a_m}\) is the prime factorization of an odd composite positive integer. Let \(y\) be an integer chosen uniformly at random, subject to the requirements that \(1 \leq y \leq N - 1\) and \(y\) is co-prime to \(N\), namely \(\gcd(y, N) = 1\). Let \(r\) be the order of \(y\) modulo \(N\), that is the least positive integer such that \(y^r \pmod N = 1\). Then the probability that \(r\) is even and \(y^{r/2} \neq -1 \pmod N\) satisfies:

\[
p\left(r \text{ even and } y^{r/2} \neq -1 \pmod N\right) \geq 1 - \frac{1}{2^m}\]  

(4.15)

Therefore, the factorizing problem is equivalent to find the order \(r\) of random number \(y\) modulo \(N\) [note that if \(y = 1\), its order is \(r = 1\), being \(1^r \pmod N = 1, \forall r > 0\)]; if \(r\) is even and \(x = y^{r/2}\) is not a trivial solution of \(x^2 = 1 \pmod N\), and this is quite likely according to Theorem 4.2, then we can apply Theorem 4.1, that is, one of \(\gcd(x - 1, N)\) and \(\gcd(x + 1, N)\) is a non-trivial factor of \(N\).

4.3.1 Order-finding protocol

To find the order of \(x \pmod N\) is a hard problem on a classical computer, since there is not an algorithm to solve this problem using resources polynomial in \(O(L)\), where \(L = \lceil \log_2 N \rceil\) is the number of bits needed to specify \(N\). In the following we investigate the performance of a quantum algorithm.

We start from a unitary operator \(\hat{U}_x\) such that:

\[
\hat{U}_x|y\rangle_L = |xy \pmod N\rangle_L,
\]
where \( 0 \leq y < 2^L \). In Fig. 4.7 we report the quantum circuits representing the action of \( \hat{U}_s \). Let us now consider the state:

\[
|u_r(x, r)\rangle_L = \frac{1}{\sqrt{r}} \sum_{k=0}^{r-1} e^{-2\pi i k s / r} |x^k (\text{mod } N)\rangle_L
\]

with \( 0 < s < r \) integer and \( r \) is the (unknown!) order of \( x \) modulo \( N \), namely, \( x^r (\text{mod } N) = 1 \). Note that \( L \langle u_l(x, r) | u_r(x, r) \rangle_L = \delta_{l,s} \). We have:

\[
\hat{U}_s |u_s(x, r)\rangle_L = \frac{1}{\sqrt{r}} \sum_{k=0}^{r-1} e^{-2\pi i k s / r} |x^{k+1} (\text{mod } N)\rangle_L
\]  

which can be rewritten as:

\[
\hat{U}_s |u_s(x, r)\rangle_L = \frac{1}{\sqrt{r}} \sum_{k=1}^{r} e^{-2\pi i (k-1) s / r} |x^k (\text{mod } N)\rangle_L
\]  

wherever and to pass from Eq. (4.18) to Eq. (4.19) we used \( |x^r (\text{mod } N)\rangle_L = |x^0 (\text{mod } N)\rangle_L = 1 \) and introduced \( \phi_s(r) = s / r \). It follows that \( |u_s(x, r)\rangle_L \) is an eigenstate of \( \hat{U}_s \) with eigenvalue \( \exp (2\pi i r s) \). Therefore, we can estimate the ratio \( \phi_s(r) = s / r \) applying the phase-estimation procedure described in section 4.2. The quantum circuit implementing the order-finding procedure is sketched in Fig. 4.8.

Indeed, we should be able to implement the controlled-\( \hat{U}_s^k \) gates, and this is fine. The issue could be the preparation of the eigenstate \( |u_s(x, r)\rangle_L \). However we note that:

\[
\frac{1}{\sqrt{r}} \sum_{s=0}^{r-1} |u_s(x, r)\rangle_L = \frac{1}{r} \sum_{k=0}^{r-1} \sum_{s=0}^{r-1} e^{-2\pi i k s / r} |x^k (\text{mod } N)\rangle_L = |1\rangle_L.
\]
Therefore, after the controlled-Û, where:

We can calculate the action of the controlled-U on the state \( |\psi^s\rangle\), we can rewrite the state (4.22) as follows:

\[
\sum_{z=0}^{2^n-1} |z\rangle_R |s\rangle_L \rightarrow |z\rangle_R \hat{U}_k^{z_0} \cdots \hat{U}_k^{z_n} |y\rangle_L
\]

Now we investigate how to implement a quantum circuit for the order-finding procedure. As for the usual phase-estimation protocol, we start from the input state \( |0\rangle_n |1\rangle_L \) and apply \( H^{\otimes n} \) to the first register, that is to \( |0\rangle_n \), obtaining the balanced superposition of all the integers from 0 to \( 2^n - 1 \):

\[
\frac{1}{2^{n/2}} \sum_{z=0}^{2^n-1} |z\rangle_R |1\rangle_L.
\]

We can calculate the action of the controlled-\( U^k_L \), \( k = 0, \ldots, n-1, \) on \( |1\rangle_L \), where, for a given \( |z\rangle_R = |z_0\rangle \cdots |z_{n-1}\rangle \), \( z = \sum_{h=0}^{n-1} z_h 2^h \), the control qubit is \( |z_k\rangle \). In general we can write:

\[
|z\rangle_R |y\rangle_L \rightarrow |z\rangle_R \hat{U}_k^{z_0} \cdots \hat{U}_k^{z_{n-1}} |y\rangle_L
\]

\[
|z\rangle_R |x^2 y (\text{mod} N)\rangle_L.
\]

Therefore, after the controlled-\( \hat{U}_k^{z^n} \) we have the final state (before the inverse of QFT):

\[
\frac{1}{2^{n/2}} \sum_{z=0}^{2^n-1} |z\rangle_R |x^2 (\text{mod} N)\rangle_L.
\]

(4.22)

Since \( |x^2 (\text{mod} N)\rangle_L = U^r_L |1\rangle_L \) and \( |1\rangle_L \) can be written as a balanced superposition of \( |u_s(x, r)\rangle \), as show in Eq. (4.21), we can rewrite the state (4.22) as follows:

\[
\frac{1}{\sqrt{r}} \sum_{z=0}^{r-1} |\psi [\phi_s (r)]\rangle_R |u_s(x, r)\rangle_L,
\]

(4.23)

where:

\[
|\psi [\phi_s (r)]\rangle_R = \frac{1}{2^{n/2}} \sum_{z=0}^{2^n-1} \exp [2\pi i z \phi_s (r)] |z\rangle_R,
\]

that has the same form as in Eq. (4.6). If we now suppose to measure (implicit measurement) the output register and to find as outcome the state \( |u_s(x, r)\rangle_L \) (with probability 1/r), then the input
register is left in the state $|Ψ[φ_s(r)]⟩_n$. It is now clear that $F_Q^† |Ψ[φ_s(r)]⟩_n$ leads to an estimation of $φ_s(r)$ as shown in the next section.

We have seen how the order-finding problem is reduced to a phase estimation process, where the unknown phase to be estimated is $φ_s(r) = s/r$. Of course, at the end of the protocol we obtain an estimated value $φ$ of $φ_s(r)$, where both $s$ and $r$ are unknown, thus we should find a way to retrieve this information starting from $φ$. This will be shown in section 4.3.2.

4.3.2 Continued-fraction algorithm

First of all we recall that the continued-fraction algorithm describes a positive real number $z$ in terms of positive integers $[a_0, a_1, \ldots, a_M]$, where $a_0 \geq 0$ and $a_k > 0$, $k > 0$, namely:

$$z \rightarrow [a_0, a_1, \ldots, a_M] = a_0 + \frac{1}{a_1 + \frac{1}{a_2 + \frac{1}{\ldots + \frac{1}{a_M}}}}. \quad (4.24)$$

The $m$-th convergent to the continued fraction $[a_0, a_1, \ldots, a_M]$ is $[a_0, \ldots, a_m]$, with $0 \leq m \leq M$. Furthermore, if $z = S/R$, where $S$ and $R$ are $L$-bit integers, then the algorithm requires $O(L^3)$ operations.

□ - Example 4.4 $z = 2.93 \rightarrow [2, 1, 13, 3, 2]$.

□ - Example 4.5 Decomposition of a fraction as a continued fraction.

$$z = \frac{31}{13} = 2.384615 \rightarrow [2, 2, 1, 1, 2].$$

In order to find the fraction $s/r$ corresponding to the estimated phase $φ$ of $φ_s(r)$, we can use the following theorem:

**Theorem 4.3** If

$$\left| \frac{s}{r} - φ \right| \leq \frac{1}{2^L} \quad (4.25)$$

then $s/r$ is a convergent of the continued fraction for $φ$ and can be computed with $O(L^3)$ operations using the continued-fraction algorithm.

In order to apply the Theorem 4.3 we should satisfy the condition in Eq. (4.25); in our case $N$ is an $L$-bit integer, $r \leq N \leq 2^L$, and we, thus, have:

$$\frac{1}{2^L} \geq \frac{1}{2^{2L+1}}. \quad (4.26)$$

Therefore, if we use $n = 2L + 1$ bits for the register involved in the estimation of $φ_s(r)$, on the one hand the accuracy in the estimation of the best $φ^{(b)}$ is $2^{-(2L+1)}$, that is:

$$\left| φ^{(b)} - φ \right| \leq \frac{1}{2^{2L+1}},$$
and, on the other hand, Ineqs. (4.26) allow us to write:

\[ |\phi^{(b)} - \phi| \leq \frac{1}{2^r}, \]  

(4.27)

and, thus, we can apply the Theorem 4.3 finding the two integers \( s \) and \( r \) such that:

\[ \phi^{(b)} = \frac{s}{r}. \]

In particular we obtained the order \( r \) and we can check whether \( x^r (\mod N) = 1 \).

### 4.3.3 The factoring algorithm

We can now summarize the procedure to factor an integer \( N \):

1. If \( N \) is even, return the factor 2.

2. Determine whether \( N = a^b \) for integers \( a \geq 1 \) and \( b \geq 2 \), and if so return the factor \( a \) (this can be done with a classical algorithm).

3. Randomly choose an integer \( y \in [1, N - 1] \). If gcd\((y, N) > 1\) then return the factor gcd\((y, N)\).

4. If gcd\((y, N) = 1\), use the order-finding subroutine to find the order \( r \) of \( y \) modulo \( N \) (here quantum mechanics help us).

5. If \( r \) is even and \( x = y^{r/2} \neq -1 (\mod N) \), then compute gcd\((x - 1, N)\) and gcd\((x + 1, N)\), and test to see if one of these is a non-trivial factor \( N \), returning that factor if so (see Theorem 4.1). Otherwise, the algorithm fails.

### 4.3.4 Example: factorization of the number 15

The smallest integer number which is not even or a power of some smaller integer is the number \( N = 15 \), thus we can apply the order-finding protocol in order to factorize it.

Since \( N = 15 \), we have \( L = \lceil \log_2 15 \rceil = 4 \). Therefore, if we require a success probability of at least \( 1 - \varepsilon = 3/4 \), corresponding to an error probability of at most \( \varepsilon = 1/4 \), the number of qubits needed for the first register is:

\[ n = 2L + 1 + \left\lfloor \log_2 \left( 2 + \frac{1}{2\varepsilon} \right) \right\rfloor = 11, \]

where the term \( 2L + 1 \) is needed to apply the continued-fraction algorithm (see section 4.3.2).

We proceed as follows.

1. We generate the random number \( y \in [1, N - 1] \equiv [1, 14] \), for instance, we get \( y = 7 \).
2. We use the order-finding protocol to find the order \( r \) of \( y (\mod N) \). The initial state is \( |0\rangle_{11} |1\rangle_4 \) and after the application of the Hadamard transformations and the controlled-\( \hat{U}^2 \) gates (but before the inverse of the QFT, see Fig. 4.8), we obtain the state:

\[
\frac{1}{\sqrt{2048}} \sum_{z=0}^{2047} |z\rangle_{11} |y^z (\mod N)\rangle_4
\]

which explicitly writes:

\[
\frac{1}{\sqrt{2048}} (|0\rangle_{11} |1\rangle_4 + |1\rangle_{11} |7\rangle_4 + |2\rangle_{11} |4\rangle_4 + |3\rangle_{11} |13\rangle_4
+ |4\rangle_{11} |1\rangle_4 + |5\rangle_{11} |7\rangle_4 + |6\rangle_{11} |4\rangle_4 + |7\rangle_{11} |13\rangle_4 + \ldots).
\]

or, in a more compact form:

\[
\frac{1}{\sqrt{512}} \sum_{k=0}^{511} \frac{1}{2} (|4k\rangle_{11} |1\rangle_4 + |1 + 4k\rangle_{11} |7\rangle_4 + |2 + 4k\rangle_{11} |4\rangle_4 + |3 + 4k\rangle_{11} |13\rangle_4),
\]

where we put in evidence four contributions. Now we should apply \( \hat{F}_Q^\dagger \) to the first register. However, since the second register does not undergo further transformations, we can assume that it is measured before the application of the inverse of the QFT: this does not affect the success of the protocol but simplifies the theoretical calculations. The measurement outcome will be one of the four possible states \( |1\rangle_4, |7\rangle_4, |4\rangle_4 \) or \( |13\rangle_4 \) with probability 1/4. Suppose we get \( |4\rangle_4 \), thus the first register is left into the state (similar results follows from the other outcomes):

\[
|\Psi[\phi_s(r)]\rangle_{11} = \frac{1}{\sqrt{512}} \sum_{k=0}^{511} |2 + 4k\rangle_{11}.
\]

After the inverse of the QFT the previous state of the first register is transformed into the superposition:

\[
\hat{F}_Q^\dagger |\Psi[\phi_s(r)]\rangle_{11} = \frac{1}{\sqrt{512}} \sum_{k=0}^{511} \frac{1}{\sqrt{2048}} \sum_{z=0}^{2047} \exp \left( -2\pi i z \frac{2 + 4k}{2048} \right) |z\rangle_{11}
= \sum_{z=0}^{2047} c_z |z\rangle_{11}
= |0\rangle_{11} - |512\rangle_{11} + |1024\rangle_{11} - |1536\rangle_{11}.
\]

where we introduced:

\[
c_z = \frac{1}{1024} \sum_{k=0}^{511} \exp \left( -2\pi i z \frac{2 + 4k}{2048} \right) = \frac{e^{i\pi z}}{1024} \cos \left( \frac{\pi z}{512} \right) \sin \left( \frac{\pi z}{512} \right),
\]
which is non null only if $z$ is an integer multiple of 512, namely, $z = 0, 512, 1024, 1536$. Therefore we have:

$$\hat{f}_Q^\dagger |\Psi[\phi_s(r)]\rangle_{11} = \frac{|0\rangle_{11} - |512\rangle_{11} + |1024\rangle_{11} - |1536\rangle_{11}}{2}.$$  

The measurement on the first register gives with probability 1/4 one of the four states and let’s suppose that we obtain $|1536\rangle_{11}$ (similar results are obtained for $|512\rangle_{11}$). Since $2^{11} = 2048$, our outcome leads to the continued-fraction expansion $1536/2048 = 3/4$ and, therefore, the order of $y = 7$ modulo $N = 15$ is $r = 4$ (the denominator of the fraction), which is even!

3. Since the order $r$ is even and $y^{r/2} = 7^2 = 49 \equiv 1 (\text{mod } 15)$, $x = y^{r/2}$ is a solution of $x^2 = 1 (\text{mod } N)$ and we can apply the Theorem 4.1 obtaining:

$$\text{gcd}(x - 1, N) = \text{gcd}(48, 15) = 3,$$

$$\text{gcd}(x + 1, N) = \text{gcd}(50, 15) = 5.$$

Finally: $15 = 3 \times 5$.

In the other two cases, namely, $|0\rangle_{11}$ and $|1024\rangle_{11}$, the algorithm fails. In fact, if $|0\rangle_{11}$ it is not possible to retrieve the information about $r$. In the case of $|1024\rangle_{11}$ we have the continued-fraction expansion $1024/2048 = 1/2$, therefore $r = 2$, that is even, $x = y^{r/2} = 7$ but $7^2 (\text{mod } 15) = 4 \neq 1$ and the algorithm fails.

Chapter 4: The Quantum Fourier Transform and the factoring algorithm
Chapter 5

The quantum search algorithm

In this chapter we address the quantum solution to the search problem. In particular we focus on the search through a search space of $N = 2^n$ elements, where each element is identified by an integer index $x \in \Omega = \{0, 1, \ldots, N - 1\}$ and, thus, by the state $|x\rangle_n$, and we assume that the search has $M$ solutions. We can represent the instance of the search problem by means of a function $f : \{0, 1, \ldots, N - 1\} \rightarrow \{0, 1\}$ such that:

$$f(x) = 0 \Rightarrow x \text{ is not a solution,}$$
$$f(x) = 1 \Rightarrow x \text{ is a solution.}$$

Indeed, we also need an oracle able to recognize the solutions to the search problem. As usual, we assume that the oracle acts as follows:

$$|x\rangle_n|q\rangle \hat{O} \rightarrow |x\rangle|q \oplus f(x)\rangle,$$

where $\hat{O}$ is the quantum operator associated with the oracle and $|q\rangle$ is the oracle qubit, $q \in \{0, 1\}$. Note that $|q\rangle \rightarrow |q\rangle$ only if $f(x) = 1$, namely, only if $x$ is a solution. Due to the linearity, we also have:

$$|x\rangle_n \frac{|0\rangle - |1\rangle}{\sqrt{2}} \hat{O} \rightarrow |x\rangle_n \frac{|0 \oplus f(x)\rangle - |1 \oplus f(x)\rangle}{\sqrt{2}} = (-1)^{f(x)} |x\rangle_n \frac{|0\rangle - |1\rangle}{\sqrt{2}}.$$

Since the state of the oracle qubit is left unchanged, we can focus only on the $|x\rangle$. We have:

$$|x\rangle_n \hat{O} \rightarrow |x\rangle_n \text{ if } x \text{ is not a solution,}$$
$$|x\rangle_n \hat{O} \rightarrow -|x\rangle_n \text{ if } x \text{ is a solution,}$$

that is, the oracle marks a solution $x$ to the problem by shifting the phase of the corresponding qubit state $|x\rangle$. It is worth noting that the oracle does not know the solution: it is just able to recognize a solution.
5.1 Quantum search: the Grover operator

We start our search procedure with the \( n \) qubits prepared in the state \( |0\rangle_n \) and, then, we apply \( n \) Hadamard transformations in order to generate a superposition of all the possible states:

\[
H^\otimes n |0\rangle_n = \frac{1}{\sqrt{2^n}} \sum_{x=0}^{2^n-1} |x\rangle_n = |\psi\rangle_n.
\]

Now we apply the so-called Grover iteration or Grover operator \( \hat{G} \) which consists in the following steps:

- apply the oracle (this needs also the additional oracle qubit that we do not consider explicitly): \( |x\rangle_n \rightarrow (−1)^{f(x)} |x\rangle_n \);
- apply \( H^\otimes n \);
- apply the conditional shift \( |x\rangle_n \rightarrow (−1)^{1+\delta_{x,0}} |x\rangle_n \), i.e., all the states but \( |0\rangle_n \) which is left unchanged, undergo a phase shift;
- apply \( H^\otimes n \).

Note that the conditional phase shift can be described by the unitary operator \( 2|0\rangle_n \langle 0| - \hat{I} \).

Furthermore, we have:

\[
H^\otimes n (2|0\rangle_n \langle 0| - \hat{I}) H^\otimes n = 2|\psi\rangle_n \langle \psi| - \hat{I},
\]

therefore, the Grover operator can be written as:

\[
\hat{G} = [(2|\psi\rangle_n \langle \psi| - \hat{I}) \otimes \hat{I}] \hat{O}.
\]

In the following we see that by applying \( \hat{G} \) a certain number of times, one obtains a solution to the search problem with high probability.

5.1.1 Geometric interpretation of the Grover operator

By definition, the state \( |\psi\rangle_n \) is a superposition of all the possible states \( |x\rangle_n \), \( x \in \Omega \). However, we can introduce the two sets \( A \) and \( B \), \( A \cup B = \Omega \) and \( A \cap B = \emptyset \), such that:

- if \( x \in A \) then \( f(x) = 0 \Rightarrow x \) is not a solution,
- if \( x \in B \) then \( f(x) = 1 \Rightarrow x \) is a solution.

Therefore we can define the two orthogonal states:

\[
|\alpha\rangle_n = \frac{1}{\sqrt{N-M}} \sum_{x \in A} |x\rangle_n, \quad \text{and} \quad |\beta\rangle_n = \frac{1}{\sqrt{M}} \sum_{x \in B} |x\rangle_n,
\]
Quantum search: the Grover operator

Figure 5.1: Geometric representation of the action of the Grover operator onto the state $|\psi\rangle_n$ (gray vector): (left) initial state; (center) after the oracle call the initial state is reflected across the direction of the $|\alpha\rangle_n$; (right) after the application of the operator $2|\psi\rangle_n\langle\psi| - \hat{I}$ the final state is nearer to the vector of solution $|\beta\rangle_n$. The overall effect of a single application of the Grover operator is a counterclockwise rotation of amount $\theta$ applied to the initial state $|\psi\rangle_n$.

where $|\alpha\rangle_n$ represents the superposition of all the states $|x\rangle_n$ which are not solutions, while $|\beta\rangle_n$ is the superposition of all the states $|x\rangle_n$ which are solutions to the search problem. Of course we have:

$$|\psi\rangle_n = \sqrt{\frac{N-M}{N}} |\alpha\rangle_n + \sqrt{\frac{M}{N}} |\beta\rangle_n.$$  

Since we reduced our $N$-dimensional system to a two-dimensional one, we can also introduce the following parameterization:

$$|\psi\rangle_n = \cos \frac{\theta}{2} |\alpha\rangle_n + \sin \frac{\theta}{2} |\beta\rangle_n,$$

with:

$$\cos \frac{\theta}{2} = \sqrt{\frac{N-M}{N}}, \quad \text{and} \quad \sin \frac{\theta}{2} = \sqrt{\frac{M}{N}}.$$

We can represent the states $|\alpha\rangle_n$, $|\beta\rangle_n$, and $|\psi\rangle_n$ in a two-dimensional (real) space, as shown in the left panel of figure 5.1. This allows us to obtain a geometrical interpretation of the action of the Grover algorithm. After the query to the oracle we have $|\beta\rangle_n \rightarrow -|\beta\rangle_n$, therefore, the state $|\psi\rangle_n$ is reflected across the direction of the vector associated with $|\alpha\rangle_n$ (figure 5.1, center panel). Now we should apply $2|\psi\rangle_n\langle\psi| - \hat{I}$, which corresponds to a reflection across the direction of the vector associated with $|\psi\rangle_n$ (right panel of figure 5.1). Overall, the action of $\hat{G}$ on $|\psi\rangle_n$ after a single iteration can be summarized as follows (recall that we are not explicitly considering the oracle qubit, which is indeed necessary to apply $\hat{O}$):

$$|\psi\rangle_n = \cos \frac{\theta}{2} |\alpha\rangle_n + \sin \frac{\theta}{2} |\beta\rangle_n \rightarrow 2|\psi\rangle_n\langle\psi| - \hat{I} |\psi\rangle_n^{(1)} = \cos \frac{3\theta}{2} |\alpha\rangle_n + \sin \frac{3\theta}{2} |\beta\rangle_n,$$

thus, from the geometrical point of view, the action of the Grover operator onto a state is a
counterclockwise rotation of an amount \( \theta \), described by the matrix:
\[
\hat{G} \rightarrow \begin{pmatrix}
\cos \theta & -\sin \theta \\
\sin \theta & \cos \theta
\end{pmatrix}.
\] (5.1)

After \( k \) iterations we find:
\[
|\psi_n\rangle \xrightarrow{\hat{G}^k} |\psi_n^{(k)}\rangle = \cos \left( \frac{2k + 1}{2} \theta \right) |\alpha_n\rangle + \sin \left( \frac{2k + 1}{2} \theta \right) |\beta_n\rangle.
\]

It is worth noting that \( \theta \) is a function of both \( N \), the total number of states, and of the number of solutions \( M \).

\[\square - \text{Exercise 5.1} \] By using the geometrical representation, prove that 
\[2|\psi_n\rangle \langle \psi| - \hat{I}\]
corresponds to a reflection across the direction of the vector associated with \( |\psi_n\rangle \).

### 5.2 Number of iterations and error probability

As a matter of fact, we have a best number \( R \) of Grover iterations, which bring the initial state \( |\psi_n\rangle \), as nearer as possible to the state \( |\beta_n\rangle \): further iterations would drive the state away from \( |\beta_n\rangle \). Thanks to the geometrical interpretation (see again the left panel of figure 5.1) we find that in order to obtain exactly \( |\beta_n\rangle \) we should rotate \( |\psi_n\rangle \) by an amount \( \phi = \arccos \sqrt{M/N} \).

Therefore the number of needed iterations is:
\[
R = \text{CI} \left( \frac{\arccos \sqrt{M/N}}{\theta} \right),
\]
where \( \text{CI}(z) \) corresponds to the closest integer to the real number \( z \). After this number of iterations, one measures the final state in the computational basis and obtains a solution to the search problem with a high probability.

In particular, if \( M \ll N \), we have that the angular error in the final state will be at most \( \theta/2 \approx \sqrt{M/N} \), and the probability of error is thus given by:
\[
P_{\text{err}} = \left| \sin \frac{\theta}{2} \right|^2 \approx \frac{M}{N} \ll 1.
\]

Furthermore, since:
\[
R = \text{CI} \left( \frac{\arccos \sqrt{M/N}}{\theta} \right) \leq \left\lceil \frac{\pi}{2\theta} \right\rceil,
\]
assuming \( M \leq N/2 \) we find \( \theta/2 \geq \sin(\theta/2) = \sqrt{M/N} \) and we have the following bound on the best number of iterations, i.e.:
\[
R \leq \left\lceil \frac{\pi}{2\theta} \right\rceil \leq \left\lceil \frac{\pi}{4} \sqrt{\frac{N}{M}} \right\rceil.
\]
that is $R \sim O(\sqrt{N/M})$, while a classical algorithm would solve the search problem with $O(N)$ steps. It is worth noting that since:

$$\sin \theta = \frac{2\sqrt{M(N-M)}}{N},$$

(5.2)

on the one hand if $M \leq N/2$, then $\theta$ grows with the number of solutions $M$, thus requiring less iterations; on the other hand, if $N/2 < M \leq N$, then $\theta$ decreases as $M$ increases, namely, more iterations are required (see figure 5.2). This is a silly property of the quantum search algorithm, which can be solved by increasing the total number of state from $N = 2^n$ to $2N = 2^{n+1}$, that is, we just add one qubit.

## 5.3 Quantum counting

Up to now we addressed the search problem assuming that the number of solutions, and, thus, $\theta$, was known. In general this is not the case. Nevertheless, it is possible to estimate both $\theta$ and $M$, and this allows us to find a solution quickly and also to decide whether or not a solution even exists!

In section 5.1.1 we have seen that in the space spanned by $|\alpha\rangle_n$ and $|\beta\rangle_n$, $\hat{G}$ behaves as a rotation described by the $2 \times 2$ matrix of Eq. (5.1). It is straightforward to see that $e^{i\theta}$ and $e^{i(2\pi - \theta)}$ are the eigenvalues of $\hat{G}$, therefore we can apply the phase estimation protocol described in section 4.2 in order to estimate $\theta$ and $M$. For ease the analysis, we double $N$ by adding a qubit in order to be assured that the number of solution $M$ is less then the half of the possible states, that is $2N$. Now, we have $\sin^2(\theta/2) = M/(2N)$.

Following section 4.2, if we want an accuracy to $m$ bits, namely, $|\Delta \theta| \leq 2^{-m}$, with success probability $1 - \epsilon$, we need to use a register with at least a number of qubits given by Eq. (4.13). By using $\sin^2(\theta/2) = M/(2N)$ one can show that:

$$|\Delta M| < \left(2\sqrt{NM} + \frac{N}{2^{m+1}}\right) 2^{-m}.$$
5.4 Example of quantum search

As an example of quantum search we consider a 2-bit search space, that is $N = 2^2$ and we assume to know that there is only one solution to the problem, that is $x_0 \in \{0, 1, 2, 3\}$. From the classical point of view one would need on average 2.25 oracle calls. What is the performance of the quantum algorithm?

We start, as usual, with the superposition:

$$|\psi\rangle_2 = \frac{1}{2} \sum_{x=0}^{3} |x\rangle_2 = \frac{\sqrt{3}}{2} |\alpha\rangle_2 + \frac{1}{2} |\beta\rangle_2,$$  \hspace{1cm} (5.3)

where $|\alpha\rangle_2 = 3^{-1/2} \sum_{x \neq x_0} |x\rangle_2$ and $|\beta\rangle_2 = |x_0\rangle_2$. Since $\sin(\theta/2) = 1/2$, we have $\theta = \pi/3$, and, therefore, we need just one iteration of $\hat{G}$ with $\theta = \pi/3$ obtaining the following evolution:

$$|\psi\rangle_2 \xrightarrow{\hat{G}} |x_0\rangle_2.$$

We get the right solution with only one oracle call!

\[\Box\] – Exercise 5.2 Draw the quantum circuit which implement the quantum search addressed in section 5.4.

5.5 Quantum search and unitary evolution

Suppose that $x_0 \in \{0, 1, \ldots, 2^n - 1\}$ is the label of the only solution. We guess the Hamiltonian which solves the problem of $|\psi\rangle_n$ as initial state and $|x_0\rangle_n$ as solution. Formally, we want a Hamiltonian $\hat{H}$ such that (we use natural units, i.e., $\hbar \to 1)$:

$$\exp(-i\hat{H}t) |\psi\rangle_n = |x_0\rangle_{n'},$$  \hspace{1cm} (5.5)

after a certain time evolution $t$. As a matter of fact, $\hat{H}$ should depends on both $|\psi\rangle_n$ and $|x_0\rangle_n$. Therefore, the simplest Hamiltonian we can consider is:

$$\hat{H} = |x_0\rangle_n \langle x_0| + |\psi\rangle_n \langle \psi|.$$  \hspace{1cm} (5.6)

For the sake of simplicity and to use the qubit formalism, we define the two following orthogonal states:

$$|0\rangle = |x_0\rangle_{n'} \quad \text{and} \quad |1\rangle = \frac{1}{\sqrt{N-1}} \sum_{x \neq x_0} |x\rangle_{n'},$$  \hspace{1cm} (5.7)

and we write:

$$|\psi\rangle_n = \alpha |0\rangle + \beta |1\rangle,$$

with $\alpha = \sqrt{(N-1)/N}$ and $\beta = \sqrt{1/N}$. We have:

$$\hat{H} = (\alpha^2 + 1) |0\rangle \langle 0| + \beta^2 |1\rangle \langle 1| + \alpha \beta (|0\rangle \langle 1| + |1\rangle \langle 0|).$$  \hspace{1cm} (5.8)
that is:
\[ \hat{H} = \hat{I} + \alpha (\beta \hat{\sigma}_x + \alpha \hat{\sigma}_z). \] (5.9)

It follows that [see Eq. (2.13)]:
\[ \exp(-i\hat{H}t) = e^{-it} \left[ \cos(\alpha t) \hat{I} - i \sin(\alpha t) (\beta \hat{\sigma}_x + \alpha \hat{\sigma}_z) \right], \] (5.10)

and we find the following evolution (we neglect the overall phase \( e^{-it} \)):
\[ \exp(-i\hat{H}t) |\psi\rangle_n = \cos(\alpha t) |\psi\rangle_n - i \sin(\alpha t) |x_0\rangle_n. \] (5.11)

By choosing \( t = \pi/(2\alpha) \) we have, up to an overall phase, \( |\psi\rangle_n \rightarrow |x_0\rangle_n \).

The Hamiltonian of Eq. (5.9) can be easily simulated using standard methods based on the result known as "Trotter formula":

**Theorem 5.1** Let \( \hat{A} \) and \( \hat{B} \) be Hermitian operators. Then for any real \( t \) we have:
\[ \lim_{k \to \infty} \left[ \exp\left(i\frac{\hat{A}t}{k}\right) \exp\left(i\frac{\hat{B}t}{k}\right) \right]^k = \exp \left[ i (\hat{A} + \hat{B}) t \right]. \] (5.12)

**Bibliography**

Chapter 6

Quantum operations

The quantum operation formalism allows us to describe the evolution of a quantum system in a wide variety of circumstances. In general, a quantum operation is a map $E$ that transforms a quantum state described by a density operator $\hat{\rho}$ into a new density operator $\hat{\rho}'$, i.e.:

$$E(\hat{\rho}) = \hat{\rho}'.$$ (6.1)

A quantum operation captures the dynamic change to a state which occurs as the result of some physical process. The simplest example of quantum operation is the evolution of a quantum state $\hat{\rho}$ under a unitary operator $\hat{U}$, which can be written as $E(\hat{\rho}) \equiv \hat{U}\hat{\rho}\hat{U}^\dagger$.

6.1 Environment and quantum operations

Suppose that we have a system $S$ described by $\hat{\rho}_S$ which interacts with another system $E$, which we call “environment”, described by $\hat{\rho}_E$. We assume also that the interaction is described by the unitary operator $\hat{U}$. Physically, this corresponds to describe the interaction by means of a Hamiltonian that couples the two systems, leading to their unitary evolution. If $S$ and $E$ are initially uncorrelated, and we are interested just in the evolution of the system, then its evolved state can be represented by the following map:

$$\hat{\rho}_S \rightarrow E(\hat{\rho}_S) \equiv \text{Tr}_E \left[ \hat{U}\hat{\rho}_S \otimes \hat{\rho}_E \hat{U}^\dagger \right].$$ (6.2)

Without lack of generality we assume that $\hat{\rho}_E = |e_0\rangle\langle e_0|$, where $\{|e_k\rangle\}$ is an orthonormal basis of the Hilbert space associated with the environment. Now the quantum operation in
Eq. (6.2) can be written as:

\[ \mathcal{E}(\hat{\varrho}_S) = \text{Tr}_E \left[ \hat{U} \hat{\varrho}_S \otimes |e_0\rangle\langle e_0| \hat{U}^\dagger \right] \]

\[ = \sum_k \langle e_k | \hat{U} \hat{\varrho}_S \otimes |e_0\rangle\langle e_0| \hat{U}^\dagger |e_k\rangle \]

\[ = \sum_k \hat{E}_k \hat{\varrho}_S \hat{E}_k^\dagger, \quad \text{(operator-sum representation)} \] (6.3)

where we introduced \( \hat{E}_k = \langle e_k | \hat{U} | e_0 \rangle \), that is a linear operator acting on the state space of the system \( S \). Indeed, in order to have a quantum state we should require that \( \forall \hat{\varrho}, \text{Tr}_S[\hat{\varrho}] = 1 \):

\[ 1 = \text{Tr}_S[\mathcal{E}(\hat{\varrho})] = \text{Tr}_S \left[ \sum_k \hat{E}_k \hat{\varrho} \hat{E}_k^\dagger \right] \]

\[ = \sum_k \text{Tr}_S \left[ \hat{E}_k^\dagger \hat{E}_k \hat{\varrho} \right] = \text{Tr}_S \left[ \left( \sum_k \hat{E}_k^\dagger \hat{E}_k \right) \hat{\varrho} \right], \]

therefore one should have \( \sum_k \hat{E}_k^\dagger \hat{E}_k = \hat{I} \). More in general one may have \( \sum_k \hat{E}_k^\dagger \hat{E}_k \leq \hat{I} \), and when the inequality is saturated the map is referred to as trace-preserving.

### 6.2 Physical interpretation of quantum operations

Suppose we measure the environment in the basis \( \{ |e_k\rangle \} \). The conditional state \( \hat{\varrho}_k \) of the system, corresponding to the outcome \( k \) from the measurement, is (we set \( \hat{\varrho}_S = \hat{\varrho} \)):

\[ \hat{\varrho}_k = \frac{1}{p_k} \text{Tr}_E \left[ \hat{U} \hat{\varrho}_S \otimes |e_0\rangle\langle e_0| \hat{U}^\dagger \hat{\varrho} \right] \]

\[ = \frac{1}{p_k} \langle e_k | \hat{U} \hat{\varrho}_S \otimes |e_0\rangle\langle e_0| \hat{U}^\dagger |e_k\rangle = \frac{1}{p_k} \hat{E}_k \hat{\varrho} \hat{E}_k^\dagger, \]

where \( \hat{P}_k = |e_k\rangle\langle e_k| \) and:

\[ p_k = \text{Tr}_{SE} \left[ \hat{U} \hat{\varrho}_S \otimes |e_0\rangle\langle e_0| \hat{U}^\dagger \hat{\varrho} \right], \]

\[ = \text{Tr}_S \left[ \hat{E}_k \hat{\varrho} \hat{E}_k^\dagger \right], \]

is the probability of the outcome \( k \). Therefore we have:

\[ \mathcal{E}(\hat{\varrho}) = \sum_k \hat{E}_k \hat{\varrho} \hat{E}_k^\dagger \equiv \sum_k p_k \hat{\varrho}_k, \]

and the action of \( \mathcal{E} \) is to replace \( \hat{\varrho} \) with the conditional state \( \hat{\varrho}_k \) with probability \( p_k \).
6.3 Geometric picture of single-qubit operations

As we have seen in chapter 2, we can associate the density operator $\hat{\rho}$ with a $2 \times 2$ density matrix $\rho$, which can be written as:

$$\hat{\rho} \rightarrow \rho = \frac{1}{2} \left( \mathbb{1} + r \cdot \sigma \right) = \frac{1}{2} \begin{pmatrix} 1 + r_z & r_x - ir_y \\ r_x + ir_y & 1 - r_z \end{pmatrix},$$

where $r = (r_x, r_y, r_z)$, $\sigma = (\sigma_x, \sigma_y, \sigma_z)$ are the Pauli matrices corresponding to the Pauli operators [see Eqs. (1.8)], and $r \cdot \sigma = r_x \sigma_x + r_y \sigma_y + r_z \sigma_z$. Therefore a trace-preserving quantum operation is equivalent to an affine map of the Bloch sphere into itself and can be written as $r \rightarrow r' = Mr + v$, $M$ being a $3 \times 3$ real matrix and $v$ a 3-dimensional real vector.

6.3.1 Bit flip operation

If $p$, with $0 \leq p \leq 1$, is the probability that a bit flip occurs to a qubit, that is $|0\rangle \rightarrow |1\rangle$ and $|1\rangle \rightarrow |0\rangle$, the corresponding quantum operation reads:

$$\mathcal{E}_{bf}(\hat{\rho}) = (1 - p)\hat{\rho} + p\hat{\sigma}_x \hat{\rho} \hat{\sigma}_x,$$

and the corresponding elements of the operator-sum representation are:

$$\hat{E}_0 = \sqrt{1 - p} \hat{I}, \quad \hat{E}_1 = \sqrt{p} \hat{\sigma}_x.$$

The transformation of the vector $r$ is (the proof is left to the reader):

$$r_x \rightarrow r_x,$$
$$r_y \rightarrow (1 - 2p) r_y,$$
$$r_z \rightarrow (1 - 2p) r_z,$$

that is we have a contraction of the $z$–$y$ plane by a factor $1 - 2p$, see figure 6.1.

Figure 6.1: Effect of the bit flip operation on the Bloch sphere: we have a contraction of the $z$–$y$ plane by a factor $1 - 2p$. 
6.3.2 Phase flip operation

The quantum operation corresponding to phase flip occurring with probability \( p \) is:

\[
\mathcal{E}_{\text{pf}}(\hat{\rho}) = (1 - p)\hat{\rho} + p\hat{\sigma}_z \hat{\rho} \hat{\sigma}_z,
\]

and the corresponding elements of the operator-sum representation are:

\[
\hat{E}_0 = \sqrt{1 - p} \hat{I}, \quad \text{and} \quad \hat{E}_1 = \sqrt{p} \hat{\sigma}_z.
\]

The transformation of the vector \( \mathbf{r} \) is (the proof is left to the reader):

\[
\begin{align*}
    r_x &\rightarrow (1 - 2p) r_x, \\
    r_y &\rightarrow (1 - 2p) r_y, \\
    r_z &\rightarrow r_z,
\end{align*}
\]

now we have a contraction of the \( x\text{-}y \) plane by a factor \( 1 - 2p \), as shown in figure 6.2.

6.3.3 Bit-phase flip operation

When both bit flip and phase flip operations occur with probability \( p \), the process is described by the quantum operation:

\[
\mathcal{E}_{\text{bpf}}(\hat{\rho}) = (1 - p)\hat{\rho} + p\hat{\sigma}_y \hat{\rho} \hat{\sigma}_y,
\]

and the elements of the operator-sum representation are:

\[
\hat{E}_0 = \sqrt{1 - p} \hat{I}, \quad \text{and} \quad \hat{E}_1 = \sqrt{p} \hat{\sigma}_y.
\]

The vector \( \mathbf{r} \) trasforms as follows (the proof is left to the reader):

\[
\begin{align*}
    r_x &\rightarrow (1 - 2p) r_x, \\
    r_y &\rightarrow r_y, \\
    r_z &\rightarrow (1 - 2p) r_z,
\end{align*}
\]

and, thus, we have a contraction of the \( x\text{-}z \) plane by a factor \( 1 - 2p \), see figure 6.3.
6.3 Geometric picture of single-qubit operations

Figure 6.3: Effect of the bit-phase flip operation on the Bloch sphere: we have a contraction of the x–z plane by a factor $1 - 2p$.

6.3.4 Depolarizing channel

The so-called depolarizing channel describes a process in which $\hat{\rho}$ is replaced by $\hat{I}/2$, that is the maximally mixed state, with probability $p$, namely:

$$E_{dc}(\hat{\rho}) = (1 - p)\hat{\rho} + p\hat{I}/2.$$ 

In order to obtain the operator-sum representation of the depolarizing channel, we use the following identity (the proof is left to the reader):

$$\frac{\hat{I}}{2} = \frac{1}{4}(\hat{\rho} + \hat{\sigma}_x \hat{\rho} \hat{\sigma}_x + \hat{\sigma}_y \hat{\rho} \hat{\sigma}_y + \hat{\sigma}_z \hat{\rho} \hat{\sigma}_z).$$

We find:

$$E_{dc}(\hat{\rho}) = \left(1 - \frac{3p}{4}\right)\hat{\rho} + \frac{p}{4} \sum_{k=x,y,z} \hat{\sigma}_k \hat{\rho} \hat{\sigma}_k.$$ 

or:

$$E_{dc}(\hat{\rho}) = (1 - q)\hat{\rho} + \frac{q}{3} \sum_{k=x,y,z} \hat{\sigma}_k \hat{\rho} \hat{\sigma}_k,$$

with $q = 3p/4$, which tells us that the depolarizing channel leaves $\hat{\rho}$ unchanged with probability $1 - q$, while with probability $q/3$ one of the Pauli operators is applied to it. The vector $\mathbf{r}$ evolves as follows (the proof is left to the reader):

$$
\begin{align*}
\mathbf{r}_x &\rightarrow (1 - p)\mathbf{r}_x, \\
\mathbf{r}_y &\rightarrow (1 - p)\mathbf{r}_y, \\
\mathbf{r}_z &\rightarrow (1 - p)\mathbf{r}_z,
\end{align*}
$$

therefore, we have a contraction of the whole sphere by a factor $1 - p$. Note that the maximally mixed state, in the Bloch sphere formalism, corresponds to the center of the sphere. Figure 6.4 shows the uniform contraction of the Bloch sphere under the effect of the depolarizing channel.
Figure 6.4: Effect of the depolarizing channel on the Bloch sphere: we have a uniform contraction by a factor \( p - 1 \). The center of the sphere corresponds to the qubit maximally mixed state \( \hat{I}/2 \).

### 6.4 Amplitude damping channel

Amplitude damping describes the energy dissipation (e.g., an atom which emits a photon, losses during the propagation of light, a system approaching the thermal equilibrium). The map which describes this process is:

\[
\mathcal{E}_{\text{ad}}(\hat{\varrho}) = \hat{E}_0 \hat{\varrho} \hat{E}_0^\dagger + \hat{E}_1 \hat{\varrho} \hat{E}_1^\dagger,
\]

with:

\[
\hat{E}_0 = \frac{1}{2} \left[ (1 + \sqrt{1 - \gamma}) \hat{I} + (1 - \sqrt{1 - \gamma}) \hat{\sigma}_z \right] \rightarrow \begin{pmatrix} 1 & 0 \\ 0 & \sqrt{1 - \gamma} \end{pmatrix},
\]

\[
\hat{E}_1 = \frac{\sqrt{\gamma}}{2} (\hat{\sigma}_x + i \hat{\sigma}_y) \rightarrow \begin{pmatrix} 0 & \sqrt{\gamma} \\ 0 & 0 \end{pmatrix},
\]

\( 1 \leq \gamma \leq 0 \). Note that we can also write \( \sqrt{\gamma} = \sin \theta \) and \( \sqrt{1 - \gamma} = \cos \theta \).

Exercise 6.1 Write the amplitude damping map \( \mathcal{E}_{\text{ad}}(\hat{\varrho}) \) as a function of the Pauli operators.

Since \( \hat{E}_0 = |0\rangle \langle 0| + \sqrt{1 - \gamma} |1\rangle \langle 1| \) and \( \hat{E}_1 = \sqrt{\gamma} |0\rangle \langle 1| \), it is easy to verify that:

\[
\hat{E}_0 |0\rangle = |0\rangle, \quad \text{and} \quad \hat{E}_0 |1\rangle = \sqrt{1 - \gamma} |1\rangle,
\]

and:

\[
\hat{E}_1 |0\rangle = 0, \quad \text{and} \quad \hat{E}_1 |1\rangle = \sqrt{\gamma} |0\rangle,
\]

therefore \( \gamma \) can be thought as the probability of loosing a quantum of energy. We have the following effect on the Bloch sphere:

\[
\begin{aligned}
\hat{r}_x & \rightarrow \sqrt{1 - \gamma} \hat{r}_x, \\
\hat{r}_y & \rightarrow \sqrt{1 - \gamma} \hat{r}_y, \\
\hat{r}_z & \rightarrow \gamma + (1 - \gamma) \hat{r}_z.
\end{aligned}
\]

(6.7)
In order to describe the dissipative dynamics affecting a qubit, we make the following substitution:

\[ \gamma \rightarrow \gamma(t) = 1 - e^{-t/\tau}, \] (6.8)

where \( t \) is a parameter corresponding to the time evolution and \( \tau \) is a characteristic time of the system (here we assume that \( t = 0 \) represents the initial time). Inserting \( \gamma(t) \) into Eq. (6.5) we obtain a quantum operation describing a dissipative time evolution. In particular, since:

\[ \lim_{t \to +\infty} \gamma(t) = 1, \] (6.9)

as time increases the system evolves toward the state \(|0\rangle\) (the north pole of the Bloch sphere), which is the lowest energy level of the qubit: we can now easily understand why the map of Eq. (6.5) represents dissipation... at least for a quantum system at zero temperature. Figure 6.5 shows the deformation of the Bloch sphere due to the amplitude damping channel (with asymptotic state \( \varrho_\infty = |0\rangle \langle 0| \)).

### 6.5 Generalized amplitude damping channel

In general, quantum systems may have a nonzero temperature \( T \) and, in this case, the asymptotic state does not correspond to the lowest energy one. This fact is described by means of a generalized amplitude damping channel which involves the two operators \( \hat{E}_0 \) and \( \hat{E}_1 \) of Eqs. (6.6) and the following two further operators:

\[ \hat{E}_2 = \frac{1}{2} \left[ (1 + \sqrt{1 + \gamma}) \hat{I} - (1 - \sqrt{1 - \gamma}) \hat{\sigma}_z \right] \rightarrow \begin{pmatrix} \sqrt{1 - \gamma} & 0 \\ 0 & 1 \end{pmatrix}, \] (6.10a)

\[ \hat{E}_3 = \frac{\sqrt{\gamma}}{2} \left[ \hat{\sigma}_x - i \hat{\sigma}_y \right] \rightarrow \begin{pmatrix} 0 & \sqrt{\gamma} \\ \sqrt{\gamma} & 0 \end{pmatrix}, \] (6.10b)
which represent a phase insensitive amplification process. In fact, since \( \hat{E}_2 = \sqrt{1 - \gamma} |0\rangle \langle 0| + |1\rangle \langle 1| \) and \( \hat{E}_3 = \sqrt{\gamma} |1\rangle \langle 0| \), it is easy to verify that:

\[
\hat{E}_2 |0\rangle = \sqrt{1 - \gamma} |0\rangle, \quad \text{and} \quad \hat{E}_2 |1\rangle = |1\rangle,
\]

and:

\[
\hat{E}_3 |0\rangle = \sqrt{\gamma} |1\rangle, \quad \text{and} \quad \hat{E}_3 |1\rangle = 0.
\]

The whole map reads:

\[
\mathcal{E}_{\text{gad}}(\hat{\varrho}) = p (\hat{E}_0 \hat{\varrho} \hat{E}_0^\dagger + \hat{E}_1 \hat{\varrho} \hat{E}_1^\dagger) + (1 - p) (\hat{E}_2 \hat{\varrho} \hat{E}_2^\dagger + \hat{E}_3 \hat{\varrho} \hat{E}_3^\dagger),
\]

where \( 0 \leq p \leq 1 \). If we perform the same substitution given in Eq. (6.8), we find that the stationary state for \( t \to +\infty \) is:

\[
\hat{\varrho}_\infty = \frac{1}{2} \hat{I} + \frac{2p - 1}{2} \hat{\sigma}_z \to \begin{pmatrix} p & 0 \\ 0 & 1 - p \end{pmatrix}.
\]

\( \square \) – Exercise 6.2 Find the evolution of the vector \( \mathbf{r} \) under the effect of the generalized amplitude damping channel.

### 6.5.1 Approaching the thermal equilibrium

When the quantum operation of Eq. (6.11) describes the evolution of a qubit state toward the thermal equilibrium, the probability \( p \) is a function of the temperature \( T \). If \( \varepsilon_x \) is the energy of the state \( |x\rangle, x = 0, 1 \), then one has that the state occupation probability is given by the Boltzmann distribution, namely:

\[
p_x(T) = Z \exp \left( - \frac{\varepsilon_x}{k_B T} \right),
\]

where \( Z = p_0(T) + p_1(T) \) is the partition function and \( k_B \) is the Boltzmann constant. Therefore the stationary, equilibrium state writes:

\[
\hat{\varrho}_\infty(T) \to \begin{pmatrix} p_0(T) & 0 \\ 0 & 1 - p_0(T) \end{pmatrix} = Z \begin{pmatrix} \exp[-\varepsilon_0/(k_B T)] & 0 \\ 0 & \exp[-\varepsilon_1/(k_B T)] \end{pmatrix},
\]

which represents the statistical mixture describing a two-level system at thermal equilibrium at temperature \( T \). The purity of the state \( \hat{\varrho}_\infty(T) \) is:

\[
\mu[\hat{\varrho}_\infty(T)] = 1 - 2p_0(T) p_1(T).
\]
This kind of channel describes the loss of quantum information without loss of energy. We can derive the quantum operation of this channel addressing a single qubit system subjected to a rotation around the z-axis of the Bloch sphere, namely:

$$\hat{R}_z(\theta) = \cos \theta \mathbb{1} - i \sin \theta \hat{\sigma}_z \rightarrow \begin{pmatrix} e^{-i\theta/2} & 0 \\ 0 & e^{i\theta/2} \end{pmatrix},$$

where $\theta$ is random (this is a random kick). We assume that $\theta$ is randomly distributed according to a Gaussian distribution with zero mean and variance $2\Delta^2$. We have the following evolution:

$$\hat{\rho} \rightarrow \mathcal{E}_{\text{pdc}}(\hat{\rho}) = \int_{-\infty}^{+\infty} d\theta \frac{\exp\left(-\frac{\theta^2}{4\Delta^2}\right)}{\sqrt{4\pi\Delta^2}} \hat{R}_z(\theta) \hat{\rho} \hat{R}_z(\theta)^\dagger \quad (6.12)$$

$$\mathcal{E}_{\text{pdc}}(\hat{\rho}) = \hat{E}_0 \hat{\rho} \hat{E}_0^\dagger + \hat{E}_1 \hat{\rho} \hat{E}_1^\dagger \quad (6.13)$$

with:

$$\hat{E}_0 = \sqrt{\frac{1+\exp(-\Delta^2)}{2}} \hat{\mathbb{1}}, \quad \text{and} \quad \hat{E}_1 = \sqrt{\frac{1-\exp(-\Delta^2)}{2}} \hat{\sigma}_z.$$

It is worth noting that the quantum operation of Eq. (6.13) corresponds to the phase flip operation addressed in section 6.3.2 with $p = [1 + \exp(-\Delta^2)]/2$. The effect on the Bloch sphere is analogous to that of the phase flip operation:

$$r_x \rightarrow e^{-\Delta^2} r_x,$$

$$r_y \rightarrow e^{-\Delta^2} r_y,$$

$$r_z \rightarrow r_z.$$

**Bibliography**

7 Basics of quantum error correction

7.1 The binary symmetric channel

In a classical binary symmetric channel (BSC) the information is encoded into the bits $|0\rangle$ and $|1\rangle$ and we assume that a bit flip error may occur with probability $p$. The probability of error, that is the probability that $|x\rangle \rightarrow |\bar{x}\rangle$, with $x = 0, 1$, is simply given by the bit flip probability, that is:

$$p^{(1)}_{err} = p,$$  \hspace{1cm} (7.1)

where the superscript tell us we are using just one bit to encode the information.

7.1.1 The 3-bit code

One of the classical codes used to correct the bit flip error is the 3-bit code. Here the information is encoded onto three independent copies of the original bit and the correction strategy is based on the majority voting: if, among the received three bits, at least two have the same value $x$, then we decide that the sent bit value was $x$. Indeed, here we are also assuming that only one bit undergoes bit flip and, thus, we have the following error probability, which is the probability of having two or more bits flipped:

$$p^{(3)}_{err} = p_{\geq 2} = p^3 + 3p^2(1 - p) = 3p^2 - 2p^3.$$  \hspace{1cm} (7.2)

As one can see from figure 7.1, we have that $p^{(3)}_{err} < p^{(1)}_{err}$ if $p < 1/2$.

7.2 Quantum error correction: the 3-qubit code

A quantum state cannot be cloned. Therefore we cannot have three identical copies of an unknown quantum state $|\psi\rangle$ (see section 3.3.1). Furthermore, in contrast to the classical case, we
Chapter 7: Basics of quantum error correction

Figure 7.1: Plot of $p_{\text{err}}^{(1)}$ (dashed, red line) and $p_{\text{err}}^{(3)}$ (solid, blue line) as functions of the bit flip probability $p$. For values of $p$ less than 0.5 the 3-bit code has a better performance with respect the single bit encoding.

Figure 7.2: This quantum circuit implement the transformation $|\psi\rangle|0\rangle|0\rangle \rightarrow \alpha|000\rangle + \beta|111\rangle$, where $|\psi\rangle = \alpha|0\rangle + \beta|1\rangle$.

cannot measure the state in order to get information about the error, since the measurement destroys the quantum state... We should find a quantum circuit able to “detect” the eventual error (the bit flip) and to correct it without destroying the quantum state. The solution to this problem is given by the 3-qubit code, that is the analogous of the classical code.

### 7.2.1 Correction of bit flip error

As we have seen in section 6.3.1, the evolution of a quantum state $\hat{\rho}$ through a bit flip channel can be described by the quantum map:

$$\mathcal{E}(\hat{\rho}) = (1 - p) \hat{\rho} + p \hat{\sigma}_x \hat{\rho} \hat{\sigma}_x,$$

where, now, $p$ is the bit flip probability. In the following we assume that the information is encoded in the qubit state $|\psi\rangle = \alpha|0\rangle + \beta|1\rangle$ and we also have $\hat{\sigma}_x |\psi\rangle = \alpha|1\rangle + \beta|0\rangle$. The basic idea of the 3-qubit code is to encode the information onto three qubits as follows:

$$|\psi\rangle \rightarrow |\Psi\rangle = \alpha|000\rangle + \beta|111\rangle,$$

where, as usual $|xyz\rangle = |x\rangle|y\rangle|z\rangle$. The reader can verify that this task is obtained by means of the quantum circuit of figure 7.2. It is worth noting that $|\Psi\rangle$ is an entangled state.
7.2 Quantum error correction: the 3-qubit code

Figure 7.3: The dashed box encloses the quantum circuit implementing the 3-qubit code for quantum error correction against single bit flip operation.

As in the classical case, we let the bit flip channel affect independently each qubit (uncorrelated channels). After the noisy evolution we should implement the error diagnosis and correction: in figure 7.3 we can see the quantum circuit achieving this goal.

In order to understand how the 3-qubit code works, let us assume that after the bit flip channel the state is \( |\Psi'\rangle = \hat{\sigma}_x \otimes \hat{I} \otimes \hat{I} |\Psi\rangle \), i.e., the first qubit has been flipped. The first CNOT gate performs the following transformation:

\[
|\Psi'\rangle = \alpha |100\rangle + \beta |011\rangle \rightarrow \alpha |110\rangle + \beta |011\rangle,
\]

thereafter, we have the second CNOT gate which leads to:

\[
\alpha |110\rangle + \beta |011\rangle \rightarrow \alpha |111\rangle + \beta |011\rangle.
\]

The last gate is a Toffoli gate which takes the second and third qubits as control and the first qubit as target, we obtain:

\[
\alpha |111\rangle + \beta |011\rangle \rightarrow \alpha |011\rangle + \beta |111\rangle \equiv \left( \alpha |0\rangle + \beta |1\rangle \right) |11\rangle.
\]

We conclude that the error has been corrected since the state of the first qubit is still \( |\psi\rangle \).

\( \Box \) – **Exercise 7.1** Verify that the 3-qubit codes depicted in figure 7.3 works as follows:

\[
\hat{I} \otimes \hat{I} \otimes \hat{I} |\Psi\rangle \rightarrow |\psi\rangle |00\rangle,
\]

\[
\hat{\sigma}_x \otimes \hat{I} \otimes \hat{I} |\Psi\rangle \rightarrow |\psi\rangle |11\rangle,
\]

\[
\hat{I} \otimes \hat{\sigma}_x \otimes \hat{I} |\Psi\rangle \rightarrow |\psi\rangle |10\rangle,
\]

\[
\hat{I} \otimes \hat{I} \otimes \hat{\sigma}_x |\Psi\rangle \rightarrow |\psi\rangle |01\rangle.
\]

The code may fail if more than one qubit is flipped. Since the probability that at most one bit is flipped reads:

\[
p_{\leq 1} = (1 - p)^3 + 3p (1 - p)^2 = (1 - p)^2(1 + 2p),
\]
we have the following probability of error at the output:

\[ p_{\text{err},Q}^{(3)} = 1 - p_{\leq 1} = 3p^2 - 2p^3, \quad (7.9) \]

the same obtained in the classical 3-bit code.

### 7.2.2 Correction of phase flip error

Phase flip error does not have classical analogue, since the transformation \(|1\rangle \rightarrow -|1\rangle\) does not exist in classical logic. The quantum map describing a channel in which phase flip occurs with probability \(p\) reads (see also section 6.3.2):

\[ \mathcal{E}(\hat{\rho}) = (1 - p) \hat{\rho} + p \hat{\sigma}_z \hat{\rho} \hat{\sigma}_z. \quad (7.10) \]

It is worth noting that since \(\hat{\sigma}_z |x\rangle = (-1)^x |x\rangle\), we have:

\[ \hat{\sigma}_z |\pm\rangle = |\mp\rangle, \quad (7.11) \]

where:

\[ |\pm\rangle = \frac{|0\rangle \pm |1\rangle}{\sqrt{2}}, \quad (7.12) \]

and we conclude that the phase flip channel acts as a bit flip channel on the basis \(|\pm\rangle\). Therefore, recalling the action of the Hadamard transformation on the computational basis \(|0\rangle\) and \(|1\rangle\), it is easy to prove that the quantum circuit represented in figure 7.4 corrects a single phase flip error. Actually, the first Hadamard transformations physically change the computational basis in order that the phase flip channel behaves like a bit flip channel; the second Hadamard transformations transform back to the original basis in order to apply the same correction code described in the previous section.

### 7.2.3 Correction of any error: the Shor code

As a matter of fact, in a realistic channel both bit and phase flip errors may take place. It is possible to protect the qubit against the effects of an arbitrary error by means of the Shor code,
which is a combination of the 3-qubit bit flip and phase flip error correction codes. In figure 7.5 we sketched the quantum circuit implementing the Shor code. The reader can investigate its action applying the results obtained in the previous sections.

**Bibliography**

Two-level systems and basics of QED

Any two-level quantum system is associated with a Hilbert space spanned by two orthonormal states and , thus, can be seen as a qubit. In this chapter we will focus on spin particles and two-level atoms, which are the simplest example of qubits. We also explain how it is possible to manipulate spins and atoms in order to implement quantum logic gates.

8.1 Universal computation with spins

A typical two-level system is a spin particle which can be used as a qubit and manipulated by means of electromagnetic fields.

8.1.1 Interaction between a spin and a magnetic field

The operator associated with the spin magnetic moment of a spin particle is given by:

\[ \hat{\mu} = -\frac{gq}{2m} \hat{S}, \]

where \( g \) is the gyromagnetic factor (for an electron \( g \approx 2.002 \)), \( q \) and \( m \) are the charge and the mass of the particle, respectively, and \( \hat{S} = \frac{\hbar}{2} \hat{\sigma} \), where \( \hat{\sigma} = (\hat{\sigma}_x, \hat{\sigma}_y, \hat{\sigma}_z) \) is, as usual, the vector of the Pauli operators.

The Hamiltonian describing the interaction between the spin particle and the (classical) static magnetic field \( B = (B_x, B_y, B_z) \) is:

\[ \hat{H}_{\text{int}} = -\hat{\mu} \cdot B = \frac{gq}{2m} \frac{\hbar}{2} \hat{\sigma} \cdot B. \]

which can be written as:

\[ \hat{H}_{\text{int}} = \frac{\hbar \omega}{2} n \cdot \hat{\sigma}, \] 85
where we introduced the Larmor frequency \( \omega = gq|B|/(2m) \), and \( n = B/|B| \).

Without lack of generality, we assume \( B = (0,0,B) \), that is we take the magnetic field along the \( z \)-direction and, accordingly, \( n \cdot \hat{\sigma} = \hat{\sigma}_z \). Given the initial state (as we mentioned, any two-level system can be considered as a qubit, see section 2.2):
\[
|\psi_0\rangle = \cos \frac{\theta}{2} |0\rangle + \sin \frac{\theta}{2} |1\rangle,
\]
with \( \hat{\sigma}_z |x\rangle = (-1)^x |x\rangle \), \( x = 0,1 \), we have the following time evolution under the effect of \( \hat{H}_{\text{int}} \):
\[
|\psi_t\rangle = \exp \left(-i \frac{\hat{H}_{\text{int}}}{\hbar} t \right) |\psi_0\rangle
\]
\[
= \cos \frac{\theta}{2} e^{-i\omega t/2} |0\rangle + \sin \frac{\theta}{2} e^{i\omega t/2} |1\rangle
\]
\[
= e^{-i\omega t/2} \left( \cos \frac{\theta}{2} |0\rangle + \sin \frac{\theta}{2} e^{i\omega t} |1\rangle \right),
\]
where, in the last equation, the overall phase \( e^{-i\omega t/2} \) can be neglected. Following section 2.2.1, the Bloch vector \( r_t \) associated with \( |\psi_t\rangle \) reads:
\[
r_t = \begin{pmatrix}
\sin \theta \cos \omega t \\
\sin \theta \sin \omega t \\
\cos \theta
\end{pmatrix},
\]
that is we have the Larmor precession of the spin around the direction of the magnetic field (here the \( z \)-direction), as illustrated in figure 8.1.

More in general, the unitary evolution operator associated with the Hamiltonian (8.1) reads:
\[
\exp \left(-i \frac{\hat{H}_{\text{int}}}{\hbar} t \right) = \cos \left( \frac{\omega t}{2} \right) \mathbb{I} - i \sin \left( \frac{\omega t}{2} \right) n \cdot \hat{\sigma},
\]
(8.2)

and we can implement single qubit gates by suitably choosing the time \( t \) and the amplitude and orientation of the magnetic field \( B \).
8.1 Universal computation with spins

8.1.2 Spin qubit and Hadamard transformation

If we orient the magnetic field along the $x$-$z$ direction, i.e., $B = B_n$ with $n = 2^{-1/2}(1, 0, 1)$, and set the evolution time such that $\omega t = \pi$, form Eq. (8.2) we have:

$$\exp \left( -i \frac{E_{\text{int}}}{\hbar} t \right) \rightarrow -i \frac{1}{\sqrt{2}} (\hat{\sigma}_x + \hat{\sigma}_z) \equiv -i H,$$

(8.3)

that is, up to an overall phase factor “$-i$”, we have the quantum operator describing the action of the Hadamard transformation introduced in section 1.4.4 [see Eq. (1.9)].

□ – Exercise 8.1 Starting form Eq. (8.2), explain why it is possible to reproduce the action of any single-qubit gate by using a single spin and a suitably chosen classical magnetic field.

8.1.3 How to realize a CNOT gate

The CNOT gate involves two qubits and the corresponding operator, taking qubits 1 and 2 as control and target, respectively, may be written as the following operator:

$$C_{12} = \frac{1}{2} \left( \hat{I} + \hat{\sigma}_z^{(1)} + \hat{\sigma}_z^{(2)} - \hat{\sigma}_z^{(1)} \hat{\sigma}_z^{(2)} \right),$$

(8.4)

where $\hat{\sigma}_k^{(h)}$, $k = x, y, z$ and $h = 1, 2$, represent the Pauli operators acting on the $h$-th qubit (see section 1.4.2). However, as mentioned in section 3.5, $\hat{\sigma}_z = \hat{H} \hat{\sigma}_x \hat{H}$, therefore we can focus on the operator:

$$Z_{12} = (\hat{I} \otimes \hat{H}) C_{12} (\hat{I} \otimes \hat{H})$$

$$= \frac{1}{2} \left( \hat{I} + \hat{\sigma}_z^{(1)} + \hat{\sigma}_z^{(2)} - \hat{\sigma}_z^{(1)} \hat{\sigma}_z^{(2)} \right),$$

(8.5)

(8.6)

which is symmetric with respect the exchange of the two qubits. Since $(Z_{12})^2 = \hat{I}$ we have:

$$\exp (i Z_{12} \theta) = \sum_{k=0}^{\infty} \frac{(i \theta)^k}{k!} (Z_{12})^k$$

$$= \cos \theta \hat{I} + i Z_{12} \sin \theta,$$

and, setting $\theta = \pi/2$, we find:

$$Z_{12} = -i \exp \left( i Z_{12} \frac{\pi}{2} \right)$$

$$= -i \exp \left[ \frac{\pi}{4} \left( \hat{I} + \hat{\sigma}_z^{(1)} + \hat{\sigma}_z^{(2)} - \hat{\sigma}_z^{(1)} \hat{\sigma}_z^{(2)} \right) \right]$$

$$= \exp \left( -i \frac{\pi}{4} \right) \exp \left[ \frac{\pi}{4} \left( \hat{\sigma}_z^{(1)} + \hat{\sigma}_z^{(2)} - \hat{\sigma}_z^{(1)} \hat{\sigma}_z^{(2)} \right) \right].$$

Therefore, we can implement the $Z_{12}$ gate by letting the two qubits interact through the Hamiltonian:

$$\hat{H} \propto \hat{\sigma}_z^{(1)} + \hat{\sigma}_z^{(2)} - \hat{\sigma}_z^{(1)} \hat{\sigma}_z^{(2)},$$

(8.7)
and by choosing a suitable time $t$ for the corresponding unitary evolution. As we will see, the term $\hat{H}_0 \propto \sigma_z^{(1)} + \sigma_z^{(2)}$ is the free Hamiltonian of the system of the two qubits, while $\sigma_z^{(1)} \sigma_z^{(2)}$ represents a highly anisotropic interaction that couples the $z$-components of the qubits, known as Ising interaction.

Physically, the Hamiltonian $\hat{H}$ may be realized with $\frac{1}{2}$-spin particles. In this case the free Hamiltonian is $\hat{H}_0 = \frac{1}{2} \hbar (\sigma_z^{(1)} + \sigma_z^{(2)})$ and the interaction $\propto \sigma_z^{(1)} \sigma_z^{(2)}$ couples the spins along the $z$-direction subject to an uniform magnetic field, whose amplitude is proportional to the strength of their coupling. However, Ising interactions are hard to arrange and it is better to consider exchange interactions between spins. As we will see in chapter 8 (section 8.1.4), by applying suitable magnetic fields to the spins, with the same direction but different magnitudes and signs, we can build a $Z_{12}$ gate.

- Exercise 8.2 Prove that the operators $C_{12}$ and $Z_{12}$ as defined in Eqs. (8.4) and (8.6), respectively, act on $|x\rangle|y\rangle$ as a CNOT and a controlled-$Z$ gates, where $\sigma_z|x\rangle = (-1)^x|x\rangle$ and $\sigma_x|x\rangle = |\bar{x}\rangle$.

8.1.4 Exchange interactions and CNOT gate

In section 8.1.3 we have seen that CNOT may be implemented with two $\frac{1}{2}$-spins by using the Ising interaction, that is a kind of interaction which couples spin along $z$-direction. However, we pointed out that Ising interactions are hard to arrange and it is better to use exchange interactions between two spins, whose interaction Hamiltonian is:

$$\hat{H}_{\text{ex}} \propto \sigma_x^{(1)} \cdot \sigma_x^{(2)} = \sigma_x^{(1)} \sigma_x^{(2)} + \sigma_y^{(1)} \sigma_y^{(2)} + \sigma_z^{(1)} \sigma_z^{(2)},$$

where $\sigma^{(k)} = (\sigma_x^{(k)}, \sigma_y^{(k)}, \sigma_z^{(k)})$, $k = 1, 2$, is the vector of the Pauli operators acting on the Hilbert space $\mathcal{H}_k$ of the $k$-th spin.

The system we are considering here consists of two $\frac{1}{2}$-spins particles of mass $m_k$ and charge $q_k$, $k = 1, 2$. We assume that each spin interacts with a magnetic field $B_k$ whereas they are coupled through exchange interaction. The corresponding Hamiltonian reads (we use the same formalism introduced in the previous sections):

$$\hat{H} = \hbar \frac{\omega_1}{2} n_1 \cdot \sigma^{(1)} + \hbar \frac{\omega_2}{2} n_2 \cdot \sigma^{(2)} + \hbar J \sigma^{(1)} \cdot \sigma^{(2)},$$

(8.8)

where $\omega_k$ are the corresponding Larmor frequencies and $J$ is the strength of the exchange interaction. Note that if $J = 0$, then Eq. (8.8) reduces to the Hamiltonian of two uncoupled spins each interacting with the corresponding magnetic field, that is we have just two single-qubit gates.

Without lack of generality we can set $B_k = (0, 0, B_k)$ and Eq. (8.8) becomes:

$$\hat{H} = \underbrace{\hbar \frac{\omega_1}{2} \sigma_z^{(1)} + \hbar \frac{\omega_2}{2} \sigma_z^{(2)}}_{\hat{H}_0} + \hbar J \underbrace{\sigma^{(1)} \cdot \sigma^{(2)}}_{\hat{H}_{\text{ex}}},$$

(8.9)
where $H_0$ is the free Hamiltonian of the two-spin system, while $H_{\text{int}}$ is the interaction Hamiltonian. In the following we show that, starting form the Hamiltonian in Eq. (8.9), we can build the two-qubit quantum gate $Z_{12}$, that can be converted into a CNOT gate by means of Hadamard transformations realized through Eq. (8.3) (see section 8.1.3). In particular, we show that for a suitable choice of $\omega_1$ and $t$, given $J$, we may have $Z_{12} = \exp(-i \tilde{H} t / \hbar)$. First of all, we recall that:

$$Z_{12} = \frac{1}{2} \left( \hat{I} + \hat{\sigma}_z^{(1)} + \hat{\sigma}_z^{(2)} - \hat{\sigma}_z^{(1)} \hat{\sigma}_z^{(2)} \right),$$

and this is its action on the triplet states $|00\rangle$, $|11\rangle$ and $|\psi_+\rangle = 2^{-1/2}(|01\rangle + |10\rangle)$ and on the singlet state $|\psi_-\rangle = 2^{-1/2}(|01\rangle - |10\rangle)$:

$$Z_{12}|00\rangle = |00\rangle, \quad Z_{12}|11\rangle = -|11\rangle, \quad Z_{12}|\psi_+\rangle = |\psi_+\rangle, \quad Z_{12}|\psi_-\rangle = |\psi_-\rangle. \quad (8.10)$$

It is worth noting that the four states $\{ |00\rangle, |11\rangle, |\psi_\pm\rangle \}$ form a basis of the Hilbert space $H_1 \otimes H_2$, $H_0$ being the Hilbert space of the $k$-th spin. Therefore, it is enough to find the conditions on the involved parameters in order to have $\exp(-i \tilde{H} t / \hbar)$ acting as $c Z$ on such a basis.

The first step is to find the eigenvectors and eigenvalues of Eq. (8.9) and we proceed as follows. Since the SWAP operator may be written as $S = \frac{1}{2}(\hat{I} + \hat{\sigma}^{(1)} \cdot \hat{\sigma}^{(2)})$, therefore the following states are eigenstates of the operator $\hat{\sigma}^{(1)} \cdot \hat{\sigma}^{(2)}$, namely:

$$\hat{\sigma}^{(1)} \cdot \hat{\sigma}^{(2)} |00\rangle = |00\rangle, \quad \hat{\sigma}^{(1)} \cdot \hat{\sigma}^{(2)} |11\rangle = |11\rangle, \quad \hat{\sigma}^{(1)} \cdot \hat{\sigma}^{(2)} |\psi_+\rangle = |\psi_+\rangle, \quad \hat{\sigma}^{(1)} \cdot \hat{\sigma}^{(2)} |\psi_-\rangle = -3 |\psi_-\rangle. \quad (8.11)$$

Furthermore, we can write:

$$\tilde{H}_0 = \hbar \frac{\omega_+}{2} \left( \hat{\sigma}_z^{(1)} + \hat{\sigma}_z^{(2)} \right) + \hbar \frac{\omega_-}{2} \left( \hat{\sigma}_z^{(1)} - \hat{\sigma}_z^{(2)} \right),$$

with $\omega_\pm = \omega_1 \pm \omega_2$ and we find:

$$\frac{1}{2} \left( \hat{\sigma}_z^{(1)} + \hat{\sigma}_z^{(2)} \right) |00\rangle = |00\rangle, \quad \frac{1}{2} \left( \hat{\sigma}_z^{(1)} - \hat{\sigma}_z^{(2)} \right) |00\rangle = 0,$n

$$\frac{1}{2} \left( \hat{\sigma}_z^{(1)} + \hat{\sigma}_z^{(2)} \right) |11\rangle = -|11\rangle, \quad \frac{1}{2} \left( \hat{\sigma}_z^{(1)} - \hat{\sigma}_z^{(2)} \right) |11\rangle = 0,$n

$$\frac{1}{2} \left( \hat{\sigma}_z^{(1)} + \hat{\sigma}_z^{(2)} \right) |\psi_\pm\rangle = 0, \quad \frac{1}{2} \left( \hat{\sigma}_z^{(1)} - \hat{\sigma}_z^{(2)} \right) |\psi_\pm\rangle = |\psi_\pm\rangle.$n

Therefore we have:

$$\tilde{H}|00\rangle = \hbar \left( f + \frac{\omega_+}{2} \right) |00\rangle, \quad \tilde{H}|11\rangle = \hbar \left( f - \frac{\omega_+}{2} \right) |11\rangle, \quad (8.12)$$

$$\tilde{H}|\psi_+\rangle = \hbar f |\psi_+\rangle + \hbar \frac{\omega_-}{2} |\psi_-\rangle, \quad \tilde{H}|\psi_-\rangle = -3 \hbar f |\psi_-\rangle + \hbar \frac{\omega_-}{2} |\psi_+\rangle. \quad (8.13)$$
that is $|00\rangle$ and $|11\rangle$ are eigenstates of $\hat{H}$, while $\hat{H}$ transforms $|\psi_\pm\rangle$ is a linear combination of $|\psi_+\rangle$ and $|\psi_-\rangle$. Thereafter, we have the following matrix representation of $\hat{H}$ in the chosen basis:

$$\hat{H} \rightarrow \hbar \begin{pmatrix}
J + \frac{1}{2}\omega_+ & 0 & 0 & 0 \\
0 & J - \frac{1}{2}\omega_+ & 0 & 0 \\
0 & 0 & J - \frac{1}{2}\omega_- & 0 \\
0 & 0 & 0 & \frac{1}{2}\omega_- - 3J
\end{pmatrix}.$$ 

The matrix has a block-diagonal form and, to find its eigenvectors and eigenvalues we can consider only the $2 \times 2$ block [the other block is with eigenvectors and eigenvalues given in Eq. (8.12)]:

$$\begin{pmatrix}
J & \frac{1}{2}\omega_- \\
\frac{1}{2}\omega_- & -3J
\end{pmatrix}$$

that has eigenvalues $-J \pm \sqrt{4J^2 + \frac{1}{4}\omega_-^2}$, corresponding to the eigenstates $|\Psi_\pm\rangle = \alpha_\pm |\psi_+\rangle + \beta_\pm |\psi_-\rangle$, where we do not explicitly calculate the expression of the coefficients $\alpha_\pm$ and $\beta_\pm$. Now, since $|\Psi_\pm\rangle$ are eigenstates of $Z_{12}$ with eigenvalue $1$ [see Eq. (8.11)], the states $|\Psi_\pm\rangle$ are still its eigenstates with the same eigenvalue. Therefore, we have found that the four states:

$$|00\rangle, \quad |11\rangle, \quad \text{and} \quad |\Psi_\pm\rangle,$$

are eigenstates of both $Z_{12}$ and $\hat{H}$ and, thus, of the evolution operator $U_{ex}(t) = \exp(-i \hat{H}t/\hbar)$.

In order to have $Z_{12} \equiv U_{ex}(t)$, their eigenstates should have the same eigenvalues, up to a constant phase factor which should be the same for all the states, namely:

$$U_{ex}(t)|00\rangle = \exp\left[-it \left(J + \frac{1}{2}\omega_+\right)\right]|00\rangle \quad \leftrightarrow \quad Z_{12}|00\rangle = |00\rangle,$$
$$U_{ex}(t)|11\rangle = \exp\left[-it \left(J - \frac{1}{2}\omega_+\right)\right]|11\rangle \quad \leftrightarrow \quad Z_{12}|11\rangle = |11\rangle,$$
$$U_{ex}(t)|\Psi_+\rangle = \exp\left[-it \left(-J + \sqrt{4J^2 + \frac{1}{4}\omega_-^2}\right)\right]|\Psi_+\rangle \quad \leftrightarrow \quad Z_{12}|\Psi_+\rangle = |\Psi_+\rangle,$$
$$U_{ex}(t)|\Psi_-\rangle = \exp\left[-it \left(-J - \sqrt{4J^2 + \frac{1}{4}\omega_-^2}\right)\right]|\Psi_-\rangle \quad \leftrightarrow \quad Z_{12}|\Psi_-\rangle = |\Psi_-\rangle.$$ 

This happens by setting $\omega_+ = 4J$, $\omega_- = 4\sqrt{3}J$ and $t = \pi/(4J)$, which also leads to the overall constant phase factor $\exp(-i3\pi/4)$ equal for all the states. Indeed, one can change the value of $\omega_\pm$ by changing the values of the two magnetic fields. In fact, the previous conditions are equivalent to require $\omega_1 = 2(1 + \sqrt{3})J$ and $\omega_2 = 2(1 - \sqrt{3})J$, and, thus, we find (for the sake of simplicity we assume the two $\frac{1}{2}$-spin particle to be of the same species, i.e., $m_k = m, g_k = g$ and $q_k = q, k = 1, 2$):

$$B_1 = 4(\sqrt{3} + 1)\frac{mJ}{8g}, \quad \text{and} \quad B_2 = -4(\sqrt{3} - 1)\frac{mJ}{8g}.$$
Note that the two magnetic fields are directed along $z$-direction but have opposite sign; though $Z_{12}$ is symmetric, its physical implementation by means of exchange interaction requires different magnetic fields acting on the two spins. However, if we set $\omega_1 = 2(1 - \sqrt{3})f$ and $\omega_2 = 2(1 + \sqrt{3})f$ we obtain the same result, that is, the symmetry is still present!

Let us now focus on the order of magnitude of the involved quantities. The Bohr magneton and the Nuclear magneton are:

$$\mu_B = \frac{e\hbar}{2m_e} = 9.27 \times 10^{-24} \text{ J} \cdot \text{T}$$
$$\mu_N = \frac{e\hbar}{2m_p} = 5.05 \times 10^{-27} \text{ J} \cdot \text{T}$$

respectively, where $e$ is the charge of the electron while $m_e$ and $m_p$ are the masses of the electron and of the proton, respectively. Typical $\frac{1}{2}$-spin nuclei are $^1\text{H}$, $^{13}\text{C}$ and $^{19}\text{F}$ and the $J$-coupling magnitudes are $J \sim 10^8$ Hz ($\sim 100$ MHz). Since $\omega \sim 10^8$ Hz, we have that the involved magnetic field amplitudes are $\sim 10^{-2}$ T for the electronic spin and $\sim 10$ T for the nuclear spin, leading to a time-scale $t \sim 10^{-8}$ sec.

\[\square\] – Exercise 8.3

Draw the quantum circuit to implement the CNOT gate involving $\frac{1}{2}$-spin particles by using single-qubit gates and the two-qubit gate based on the exchange interaction. Explain how the involved magnetic fields should be directed, write their magnitude and the interaction time for each gate. Is it important to control the overall phases appearing on the qubit after the gates? Why?

### 8.1.5 Further considerations

The exchange interaction Hamiltonians are typical of NMR systems and molecules. The interaction between the spins is an indirect interaction mediated by the electrons shared through a chemical bond. The magnetic field seen by the nucleus is perturbed by the state of the electronic cloud, which interacts with another nucleus through the overlap of the wave-function with the nucleus (Fermi contact interaction), that is a through-bond interaction.

The same Hamiltonian of Eq. (8.8) describe the excess of electron spins in pair of quantum dots, which are linked through a tunnel junction (Heisenberg Hamiltonian). This effective Hamiltonian can be derived from a microscopic model for electrons in coupled quantum dots.

### 8.2 Interaction between atoms and light: cavity QED

In this section we address a two-level atom, throughout the section $|g\rangle$ and $|e\rangle$ represent the states associated with the ground and the excited state, respectively. The free Hamiltonian of the two-level atom can be written by means of the Pauli operators as follows:

$$\hat{H}_a = \hbar \frac{\omega_{eg}}{2} \hat{\sigma}_z,$$
where $\hbar \omega_{eg} = \hbar \omega_e - \hbar \omega_g$ is the energy difference between the two levels and we have the following association with the usual computational basis: $|e\rangle \rightarrow |0\rangle$ and $|g\rangle \rightarrow |1\rangle$.

In the two-level approximation, the electric-dipole moment operator of the atom can be written as:

$$\hat{D} = d (\varepsilon_a \hat{\sigma}_- + \varepsilon_a^* \hat{\sigma}_+)$$ (8.14)

where we introduced $\hat{\sigma}_- = |g\rangle \langle e|$ and $\hat{\sigma}_+ = |e\rangle \langle g|$, the lowering and raising operators, $d$ is the matrix element of the atomic transition and $\varepsilon_a$ is a complex vector which represents the atomic polarization transition.

### 8.2.1 Interaction picture

Given a Hamiltonian $\hat{H} = \hat{H}_0 + \hat{H}_{\text{int}}$, $\hat{H}_0$ and $\hat{H}_{\text{int}}$ being the free and interaction Hamiltonian, respectively, it is sometime useful to use the so-called interaction picture. If $|\psi_t\rangle$ represents the state of the system at the time $t$, its evolution is governed by the Schrödinger equation:

$$i \hbar \frac{\partial}{\partial t} |\psi_t\rangle = \hat{H} |\psi_t\rangle .$$

Now, we apply the following unitary transformation:

$$|\psi_t\rangle \rightarrow |\psi'_t\rangle = \hat{U}_0(t)^\dagger |\psi_t\rangle \Rightarrow |\psi'_t\rangle = \hat{U}_0(t) |\psi'_t\rangle$$

where $\hat{U}_0(t) = \exp(-i \hat{H}_0 t / \hbar)$. Substituting into the Schrödinger equation we have:

$$i \hbar \frac{\partial}{\partial t} [\hat{U}_0(t)|\psi'_t\rangle] = (\hat{H}_0 + \hat{H}_{\text{int}}) \hat{U}_0(t) |\psi'_t\rangle$$

$$\hat{H}_0 \hat{U}_0(t) |\psi'_t\rangle + i \hbar \hat{U}_0(t) \frac{\partial}{\partial t} |\psi'_t\rangle = (\hat{H}_0 + \hat{H}_{\text{int}}) \hat{U}_0(t) |\psi'_t\rangle$$

and, after some algebra and applying $\hat{U}_0^\dagger(t)$ to both sides, we obtain:

$$i \hbar \frac{\partial}{\partial t} |\psi'_t\rangle = \hat{H}'_{\text{int}}(t) |\psi'_t\rangle ,$$

where we introduced $\hat{H}'_{\text{int}}(t) = \hat{U}_0^\dagger(t) \hat{H}_{\text{int}} \hat{U}_0(t)$. Therefore, by using the interaction picture with respect to the free Hamiltonian\footnote{More in general, one can perform the interaction picture considering a different Hamiltonian which, in the case under investigation, allows to simplify the description of the system.} one can focus on the (transformed) interaction Hamiltonian: this is extremely useful in the presence of oscillatory terms as we will see in the next section where we will investigate the interaction of a two level atom with an oscillatory electric field.

### 8.2.2 Interaction between a two-level atom and a classical electric field

The interaction between a two-level atom and a classical electric field is formally equivalent to the interaction between a $\frac{1}{2}$-spin particle and a magnetic field discussed in the previous section. The quantum Hamiltonian describing the interaction between the atomic electric dipole
moment and the classical field \( E(\omega, t) = i E_0 (\epsilon_1 e^{-i\omega t - i\phi} - \epsilon_1^* e^{i\omega t + i\phi}) \) with real amplitude \( E_0 \), frequency \( \omega \) and polarization \( \epsilon_1 \), is:

\[ \hat{H}_{\text{int}} = -\hat{D} \cdot E(\omega, t), \]  

(8.15)

and the whole Hamiltonian is thus given by:

\[ \hat{H}_{\text{tot}} = \hbar \frac{\Omega' \Delta \omega}{2} \hat{\sigma}_z - \hat{D} \cdot E(\omega, t). \]  

(8.16)

In order to focus on the interaction, we consider the interaction picture with respect to the Hamiltonian \( \hat{H}_0 = \hbar \omega \hat{\sigma}_z \) (note that here we use the frequency \( \omega \) of the field). Following section 8.2.1 we have:

\[ \hat{H}_{\text{tot}} \to \hat{H} = \hat{U}_0(t) \hat{H}_{\text{tot}} \hat{U}_0^\dagger(t) = \hbar \frac{\Delta \omega}{2} \hat{\sigma}_z - \hat{U}_0(t) \hat{D} \cdot E(\omega, t) \hat{U}_0^\dagger(t), \]  

(8.17)

where \( \Delta \omega = \omega_{eg} - \omega \), that is the detuning between the two-level atom and the field. Since \( \hat{U}_0(t) \hat{\sigma}_z \hat{U}_0^\dagger(t) = \hat{\sigma}_z e^{i \omega t} \), the last term of Eq. (8.17) contains terms proportional to \( e^{\pm i\phi} \) and to \( e^{\pm i2\omega t \pm i\phi} \); these last terms are fast rotating and if we assume that the time-scale of the system is \( 1/\omega \), then their effect on the time evolution is negligible. This corresponds to perform the rotating-wave approximation (RWA) or secular approximation. Therefore, Eq. (8.16) reduces to:

\[ \hat{H} = \hbar \frac{\Omega'}{2} n \cdot \hat{\sigma}, \]  

(8.18)

where:

\[ n = \frac{1}{\Omega'} (-\Omega_0 \sin \phi, \Omega_0 \cos \phi, \Delta \omega). \]

with \( \Omega' = \sqrt{(\Delta \omega)^2 + \Omega_0^2} \) and we introduced the Rabi frequency:

\[ \Omega_0 = \frac{2d}{\hbar} E_0 \epsilon_3^* \epsilon_1. \]  

(8.19)

In the resonant case \( (\Delta \omega = 0) \) we have (we can assume \( \Omega_0 \in \mathbb{R} \) and set \( \phi = 0 \)):

\[ \hat{H} = \hbar \frac{\Omega_0}{2} \hat{\sigma}_y, \]

which has the following eigenstates \( |\gamma_{\pm}\rangle = 2^{-1/2}(|0\rangle \pm i|1\rangle) \). More in general, if \( \phi \neq 0 \), we obtain the following time evolution (still in the resonant case):

\[ \hat{U}_\phi(t) = \exp \left( -i \frac{\Omega_0 t}{2} n \cdot \hat{\sigma} \right) \]

\[ = \cos \left( \frac{\Omega_0 t}{2} \right) \hat{1} - i \sin \left( \frac{\Omega_0 t}{2} \right) \left[ -\sin \phi \hat{\sigma}_x + \cos \phi \hat{\sigma}_y \right], \]

and, by using the \( 2 \times 2 \) matrix formalism (in the computational basis):

\[ \hat{U}_\phi(t) \to \begin{pmatrix} \cos \left( \frac{\Omega_0 t}{2} \right) & -e^{-i\phi} \sin \left( \frac{\Omega_0 t}{2} \right) \\ e^{i\phi} \sin \left( \frac{\Omega_0 t}{2} \right) & \cos \left( \frac{\Omega_0 t}{2} \right) \end{pmatrix}. \]
It is now straightforward to see that:

\[ \hat{U}_\theta(t) |e\rangle = \cos \left( \frac{\Omega_0 t}{2} \right) |e\rangle + e^{i\theta} \sin \left( \frac{\Omega_0 t}{2} \right) |g\rangle, \]
\[ \hat{U}_\theta(t) |g\rangle = \cos \left( \frac{\Omega_0 t}{2} \right) |g\rangle - e^{-i\theta} \sin \left( \frac{\Omega_0 t}{2} \right) |e\rangle. \]

We have three following relevant cases.

- \( \frac{\pi}{2} \)-pulse: in this case one sets \( \Omega_0 t = \frac{\pi}{2} \) and we have the following evolution starting from \( |g\rangle \) or \( |e\rangle \):

\[ |e\rangle \rightarrow 2^{-1/2} \left( |e\rangle + e^{i\phi} |g\rangle \right), \quad \text{and} \quad |g\rangle \rightarrow 2^{-1/2} \left( |g\rangle - e^{-i\phi} |e\rangle \right), \quad (8.20) \]

and, for \( \phi = 0 \), we obtain the Hadamard transformation.

- \( \pi \)-pulse: now \( \Omega_0 t = \pi \) and we have:

\[ |e\rangle \rightarrow e^{i\phi} |g\rangle, \quad \text{and} \quad |g\rangle \rightarrow -e^{-i\phi} |e\rangle, \quad (8.21) \]

that is, besides and overall phase shift, the NOT gate.

- \( 2\pi \)-pulse: for \( \Omega_0 t = 2\pi \) we get:

\[ |e\rangle \rightarrow -|e\rangle, \quad \text{and} \quad |g\rangle \rightarrow -|g\rangle, \quad (8.22) \]

i.e., we add a phase shift to the input state. This phase shift is a well-known properties of \( 2\pi \)-spin rotations.

\[ \checkmark \text{– Exercise 8.4} \] Represent the evolution of the two-level atom interacting with a classical electric field by using the Bloch sphere formalism, in the case of \( \frac{\pi}{2} \)-pulse, \( \pi \)-pulse and \( 2\pi \)-pulse. Assume that the initial state is \( |e\rangle \), that is the north pole of the unit sphere.

### 8.2.3 Fabry-Perot cavity

The main interaction between light and atoms in quantum electrodynamics (QED) is the dipolar interaction. On the one hand, the dipole moment is fixed by the nature of the atom: usually experimentalists use the Rydberg states (that is states with very high principal quantum number \( n \) in order to obtain a high electric dipole moment) of alkali atoms, such as Rb atoms. On the other hand, one can realize a very large electric field in a narrow band of frequencies and in a small volume of space by means of a Fabry-Perot cavity.

A Fabry-Perot cavity consists of two semi-reflecting mirrors with reflectivity \( R_1 \) and \( R_2 \), respectively. In order to find the field inside the cavity, we consider what happens when two
classical fields $E_a^{(in)}$ and $E_b^{(in)}$ are mixed at a semi-reflecting mirror with reflectivity $R$ (see figure 8.2). If we denote with $E_a^{(out)}$ and $E_b^{(out)}$ the output field, we have the following linear transformation:

$$
\begin{pmatrix}
E_a^{(out)} \\
E_b^{(out)}
\end{pmatrix}
= \begin{pmatrix}
\sqrt{R} & \sqrt{1-R} \\
\sqrt{1-R} & -\sqrt{R}
\end{pmatrix}
\begin{pmatrix}
E_a^{(in)} \\
E_b^{(in)}
\end{pmatrix}
$$

that is:

$$
E_a^{(out)} = \sqrt{R}E_a^{(in)} + \sqrt{1-R}E_b^{(in)},
E_b^{(out)} = -\sqrt{R}E_b^{(in)} + \sqrt{1-R}E_a^{(in)}.
$$

The scheme of the Fabry-Perot cavity is sketched in figure 8.3: two mirrors with reflectivity $R_1$ and $R_2$, respectively, are placed at a distance $L$. The cavity is pumped with an input field $E^{(in)}$ of frequency $\omega$, which impinges on the first mirror. The transmitted part undergoes multiple reflections between the two mirrors leading to an overall forward and backward field inside the cavity, $E^{(cav)}_{\text{fwd}}$ and $E^{(cav)}_{\text{bwd}}$, respectively, an overall transmitted field $E^{(out)}$ and an overall reflected
field $E^{(\text{rfl})}$, as depicted in figure 8.3. If we define $\phi = 2L\omega/c$, then we have:

$$E^{(\text{cav})}_{\text{fwd}} = \frac{\sqrt{1-R_1}}{1+e^{i\phi}\sqrt{R_1R_2}} E^{(\text{in})},$$

$$E^{(\text{cav})}_{\text{bwd}} = e^{i\phi/2} \sqrt{R_2} E^{(\text{cav})}_{\text{fwd}},$$

$$E^{(\text{out})} = e^{i\phi/2} \sqrt{1-R_2} E^{(\text{cav})}_{\text{fwd}},$$

$$E^{(\text{rfl})} = e^{i\phi} \sqrt{(1-R_1)R_2} E^{(\text{cav})}_{\text{fwd}} + \sqrt{R_1} E^{(\text{in})}.$$  

In particular, if we assume $R_1 = R_2 = R$ and choose $L$ such that $\phi = (2m+1)\pi$ (field-cavity resonance condition), $m \in \mathbb{N}$, we obtain:

$$E^{(\text{cav})}_{\text{fwd}} = \frac{E^{(\text{in})}}{\sqrt{1-R}}, \quad (8.23a)$$

$$E^{(\text{cav})}_{\text{bwd}} = i \frac{\sqrt{R}}{\sqrt{1-R}} E^{(\text{in})}, \quad (8.23b)$$

$$E^{(\text{out})} = i E^{(\text{in})}, \quad E^{(\text{rfl})} = 0. \quad (8.23c)$$

A quantity usually considered to investigate the behavior of the cavity is the ratio between the input field power and the forward cavity field power, namely:

$$\frac{P_{\text{cav}}}{P_{\text{in}}} = \left| \frac{E^{(\text{cav})}_{\text{fwd}}}{E^{(\text{in})}} \right|^2 = \frac{1-R_1}{1+R_1R_2+2\sqrt{R_1R_2}\cos\phi}. \quad (8.24)$$

In figure 8.4 we plot $P_{\text{cav}}/P_{\text{in}}$ as a function of the input field frequency: it is clear that near resonance we have a high field amplitude inside the cavity. In order to better understand the behavior of the ratio defined in Eq. (8.24) we introduce $\delta = \phi - \pi$, i.e., the resonance is obtained...
for $\delta = 0$, and consider the limit $\delta \ll 1$. We obtain the following expression for Eq. (8.24):

$$\frac{P_{\text{cav}}}{P_{\text{in}}} = \frac{1 - R_1}{1 - \sqrt{R_1 R_2}} \frac{\Delta^2(R_1, R_2)}{\delta^2 + \Delta^2(R_1, R_2)}$$  \hspace{1cm} (8.25)

that is a Lorentzian function where the half-width at half-maximum (HWHM) is:

$$\Delta^2(R_1, R_2) = \frac{(1 - \sqrt{R_1 R_2})^2}{\sqrt{R_1 R_2}}$$

which, assuming $R_1 = R_2 = R$, reduces to:

$$\Delta(R) = \frac{1 - R}{\sqrt{R}}$$

and corresponds to a spectral bandwidth HWHM:

$$\Delta\omega = \frac{c}{2L} \frac{1 - R}{\sqrt{R}}$$

Finally, the cavity finesse is the ratio between the free spectral range, and the full-width half-maximum (FWHM) of Eq. (8.24) at resonance. In the present case the free spectral range is $2\pi c/(2L)$ (see figure 8.4), while the FWHM is $2\Delta\omega$, thus the cavity finesse is given by:

$$F = \frac{2\pi c}{2\Delta\omega} \frac{1}{2L} = \pi \frac{\sqrt{R}}{1 - R}$$

The reader can obtain a quantitative analysis of the cavities involved in typical cavity QED experiments considering that $R \approx 1$ and $L \sim 1$ cm: this is why we have a very high field amplitude inside the cavity in the microwave domain, and, remarkably, microwaves are the characteristic transition frequencies of the Rydberg states involved in these experiments.

We now focus the attention on plain waves and assume that the axis of the cavity is aligned with the $z$-axis of a reference frame, where the mirrors are placed at $z = 0$ and $z = L$, respectively. In side the cavity we have two counter propagating waves [here we also assume to be at resonance and use consider resonance and use Eqs. (8.23)]:

$$E_{\text{cav}}^{(\text{cav})}(z, \omega, t) = \frac{E^{(\text{in})}}{\sqrt{1 - R}} \cos(kz - \omega t),$$

$$E_{\text{bwd}}^{(\text{cav})}(z, \omega, t) = -\frac{E^{(\text{in})}}{\sqrt{1 - R}} \sin(kz + \omega t),$$

therefore, inside the cavity we have the following wave:

$$E_{\text{cav}}(z, \omega, t) = \frac{E^{(\text{in})}}{\sqrt{1 - R}} \left[ \cos(kz - \omega t) - \sqrt{R} \sin(kz + \omega t) \right].$$

If we now perform the time average of the intensity of the field inside the cavity, we find:

$$\langle |E_{\text{cav}}(z)|^2 \rangle \equiv \frac{\omega}{2\pi} \int_0^{2\pi/\omega} |E_{\text{cav}}(z, \omega, t)|^2 dt = \frac{1 + R - 2\sqrt{R} \sin(2kz)}{2(1 - R)} \left| E^{(\text{in})} \right|^2$$

$$= \frac{1 + R - 2\sqrt{R} \sin \left[ (2m + 1)\frac{\pi}{2L} \left| \frac{Z}{L} \right| \right]}{2(1 - R)} \left| E^{(\text{in})} \right|^2,$$
where, in the last equality, we used the resonance condition for the wave vector \( k = \omega / c \), namely \( k = (2m + 1)\pi / (2L) \). In the case of optical frequencies \( m \approx 10^5 \) and if we consider the average over the \( z \) direction we find:

\[
\langle |E_{\text{cav}}|^2 \rangle \approx \frac{1 + R}{2(1 - R)} \left| E^{(\text{in})} \right|^2.
\]

### 8.2.4 The quantum description of light

The quantum Hamiltonian of the single-mode electromagnetic field in the cavity corresponds to that of a harmonic oscillator with the same frequency \( \omega \), namely:

\[
\hat{H} = \frac{\hat{p}^2}{2} + \frac{1}{2} \omega^2 \hat{Q}^2 = \hbar \omega \left( \hat{a}^\dagger \hat{a} + \frac{1}{2} \right)
\]

where we introduced the position- and momentum-like operators:

\[
\hat{Q} = \sqrt{\frac{\hbar}{2\omega}} \left( \hat{a}^\dagger + \hat{a} \right), \quad \text{and} \quad \hat{P} = i \sqrt{\frac{\hbar \omega}{2}} \left( \hat{a}^\dagger - \hat{a} \right),
\]

respectively, \([\hat{Q}, \hat{P}] = i\hbar \hat{I}\), and:

\[
\hat{a} = \sqrt{\frac{\omega}{2\hbar}} \left( \hat{Q} + i \frac{\hat{P}}{\omega} \right), \quad \text{and} \quad \hat{a}^\dagger = \sqrt{\frac{\omega}{2\hbar}} \left( \hat{Q} - i \frac{\hat{P}}{\omega} \right),
\]

are the annihilation and creation bosonic field operators respectively. Note that \([\hat{a}, \hat{a}^\dagger] = \hat{I}\). At each mode of the radiation field corresponds a bosonic field operator.

If we denote with \( \{ |n\rangle \}_{n\in\mathbb{N}} \) the set of the eigenvectors of the self-adjoint operator \( \hat{N} = \hat{a}^\dagger \hat{a} \), namely, \( \hat{N}|n\rangle = n|n\rangle \) we have:

\[
\hat{a}|n\rangle = \sqrt{n}|n-1\rangle \quad \text{and} \quad \hat{a}^\dagger|n\rangle = \sqrt{n+1}|n+1\rangle,
\]

and, thus:

\[
|n\rangle = \frac{(\hat{a}^\dagger)^n}{\sqrt{n!}} |0\rangle,
\]

where the state \( |0\rangle \) represents the vacuum state. The set \( \{ |n\rangle \}_{n\in\mathbb{N}} \) is sometimes called Fock-state basis or photon-number basis.

### 8.2.5 The Jaynes-Cummings model

The full quantum model to describe the interaction between light and matter involves the quantum description of light. Now the classical electric field appearing in the interaction Hamiltonian of Eq. (8.15) is replaced by the corresponding quantum operator\(^2\):

\[
E = iE_0 \left( \epsilon_i \hat{a} - \epsilon_i^* \hat{a}^\dagger \right),
\]

\(^2\)We consider a stationary, time-independent cavity field and, for the sake of simplicity, we also assume that the atom is placed at the center of the cavity.
8.2 Interaction between atoms and light: cavity QED

Figure 8.5: The blue and red lines refer to the energy levels corresponding to the eigenstates of the free Hamiltonian given in Eq. (8.26) with $\omega = \omega_{eg}$: it is clear that the states $|g, n+1\rangle$ and $|e, n\rangle$, with $n \geq 0$, are degenerate. The only non-degenerate level is the ground state $|g, 0\rangle$. The Jaynes-Cummings interaction removes degeneracy and couples the dressed states $|\Psi_\pm \rangle$, whose corresponding energy levels (green lines) have an energy difference equal to $\hbar \Omega_n = \hbar \Omega_0 \sqrt{n+1}$.

where $\hat{a}$ and $\hat{a}^\dagger$ are the annihilation and creation field operators introduced in section 8.2.4. The free Hamiltonian of the system reads:

$$\hat{H}_0 = \hbar \frac{\omega_{eg}}{2} \hat{\sigma}_z + \hbar \omega \left( \hat{a}^\dagger \hat{a} + \frac{1}{2} \right),$$

(8.26)

and we have the two families of eigenstates of $\hat{H}_0$, i.e.:

$$\hat{H}_0 |g, n\rangle = h \left[ -\frac{\omega_{eg}}{2} + \omega \left( n + \frac{1}{2} \right) \right] |g, n\rangle,$$

$$\hat{H}_0 |e, n\rangle = h \left[ +\frac{\omega_{eg}}{2} + \omega \left( n + \frac{1}{2} \right) \right] |e, n\rangle,$$

where $\{|e\}, |g\rangle\}$ are the eigenstates of $\hat{\sigma}_z$, $\{|n\rangle\}$ is the photon-number basis and $|x, y\rangle = |x\rangle |y\rangle$. As we can also see in figure 8.5, if $\omega = \omega_{eg}$ the states $|g, n+1\rangle$ and $|e, n\rangle$, with $n \geq 0$, are degenerate.

The interaction Hamiltonian reads:

$$H_{int} = -\hat{D} \cdot \hat{E},$$

(8.27)

where $\hat{D}$ is still given by Eq. (8.14). By performing the interaction picture with respect to the Hamiltonian $\hat{H}' = \hbar \omega (\hat{a}^\dagger \hat{a} + \frac{1}{2} + \frac{1}{2} \hat{\sigma}_z)$ and the RWA (see sections 8.2.1 and 8.2.2), we obtain the
following interaction Hamiltonian:

\[ \hat{H}_{\text{int}} = \frac{\hbar}{2} \delta \hat{\sigma}_z - \frac{\hbar \Omega_0}{2} \left( \hat{\sigma}_+ \hat{a} - \hat{\sigma}_- \hat{a}^\dagger \right), \quad \text{Jaynes-Cummings Hamiltonian} \quad (8.28) \]

where \( \Omega_0 \) is the Rabi frequency defined in Eq. (8.19) and \( \delta = \omega_g - \omega \) is the detuning. It is interesting to note that \( \hat{H}_{\text{int}} \) couples the two-dimensional manifold spanned by \( \{ |g, n+1\rangle, |e, n\rangle \} \), with \( n > 0 \). In fact, we have:

\[ \left( \hat{\sigma}_+ \hat{a} - \hat{\sigma}_- \hat{a}^\dagger \right) |g, n+1\rangle = \sqrt{n+1} |e, n\rangle, \quad \text{(absorption of one photon)} \]

\[ \left( \hat{\sigma}_+ \hat{a} - \hat{\sigma}_- \hat{a}^\dagger \right) |e, n\rangle = -\sqrt{n+1} |g, n+1\rangle. \quad \text{(emission of one photon)} \]

Note that the ground state of the free Hamiltonian, namely, \( |g, 0\rangle \), is also an eigenstate of \( \hat{H}_{\text{int}} \).

Upon introducing the operator \( \hat{N} = \hat{a}^\dagger \hat{a} + \frac{1}{2} \hat{\sigma}_z \), the total Hamiltonian may be written as follows (after the RWA but not in the interaction picture):

\[ \hat{H} = \hbar \omega \hat{N} + \frac{\hbar}{2} \delta \hat{\sigma}_z - \frac{\hbar \Omega_0}{2} \left( \hat{\sigma}_+ \hat{a} - \hat{\sigma}_- \hat{a}^\dagger \right). \quad (8.29) \]

If we focus on the resonant case \( \delta = 0 \), besides the ground state, we find the following eigenstates of the total Hamiltonian for \( n \geq 0 \):

\[ \hat{H} |\Psi_n^\pm\rangle = \hbar \left[ (n+1) \omega \pm \frac{1}{2} \Omega_n \right] |\Psi_n^\pm\rangle, \]

where:

\[ |\Psi_n^\pm\rangle = \frac{1}{\sqrt{2}} \left( |e, n\rangle \mp i |g, n+1\rangle \right), \]

and \( \Omega_n = \Omega_0 \sqrt{n+1} \) is the Rabi frequency for \( n \) photons. The states \( |\Psi_n^\pm\rangle \) are called dressed states and \( \Delta E_n = E_n^+ - E_n^- = h \Omega_0 \sqrt{n+1} \). Of course we can also write:

\[ |e, n\rangle = \frac{1}{\sqrt{2}} \left( |\Psi_n^+\rangle + |\Psi_n^-\rangle \right), \quad \text{and} \quad |g, n+1\rangle = \frac{1}{i \sqrt{2}} \left( |\Psi_n^+\rangle - |\Psi_n^-\rangle \right). \]

- Exercise 8.5 Assume that the system is initially prepared in the state \( |e, n\rangle, n \geq 0 \). Find the probability to find the atom in the excited state after an interaction time \( t \) assuming \( \delta = 0 \).

The physical meaning of the solution of the exercise 8.5 is that the atom and the field mode exchange one single photon with frequency \( \Omega_n \).

It is worth noting that the Jaynes-Cummings Hamiltonian of Eq. (8.28) can be also written as:

\[ \hat{H}_{\text{int}} = \hbar \frac{\Omega_0}{2} \left( \hat{\sigma}_+ \hat{a} + \hat{\sigma}_- \hat{a}^\dagger \right), \]

where we perform the following unitary transformation of mode \( \hat{a} \to i \hat{a} \), which, of course, preserves the commutation relations, since \( \left[ (i \hat{a}), (i \hat{a})^\dagger \right] = [\hat{a}, \hat{a}^\dagger] = \mathbb{I} \).
8.2 Interaction between atoms and light: cavity QED

8.2.6 Vacuum Rabi oscillations: quantum circuit

If the atom is initially in the excited state \( |e\rangle \) and the field is in the vacuum state \( |0\rangle \), we have the vacuum Rabi oscillations. In particular we find:

- \( \pi \)-pulse (\( \Omega_0 t = \pi \)):
  \[ |e, 0\rangle \rightarrow |g, 1\rangle, \quad \text{and} \quad |g, 1\rangle \rightarrow -|e, 0\rangle; \]

- \( \frac{\pi}{2} \)-pulse (\( \Omega_0 t = \pi/2 \)):
  \[ |e, 0\rangle \rightarrow \frac{1}{\sqrt{2}} (|e, 0\rangle + |g, 1\rangle), \quad \text{and} \quad |g, 1\rangle \rightarrow \frac{1}{\sqrt{2}} (|g, 1\rangle - |e, 0\rangle), \]
  that are maximally entangled states of the atom and the cavity field.

\[ \Box - \text{Exercise 8.6} \quad \text{Find the effect of a} \ 2\pi \text{-pulse} \ (\Omega_0 t = 2\pi) \ \text{on} \ |e, 0\rangle \ \text{and} \ |g, 1\rangle. \]

The figure 8.6 shows how we can describe the vacuum Rabi oscillations by means of CNOT gates and controlled unitary operation:

\[ \hat{R}(t) = \exp \left( -i \frac{\Omega_0 t}{2} \hat{\sigma}_y \right) = \cos \left( \frac{\Omega_0 t}{2} \right) \hat{I} - i \sin \left( \frac{\Omega_0 t}{2} \right) \hat{\sigma}_y, \]

where we should use the following association between the physical states and the computational basis:

\[ |g, 0\rangle \leftrightarrow |00\rangle, \quad |g, 1\rangle \leftrightarrow |01\rangle, \quad |e, 0\rangle \leftrightarrow |10\rangle, \ \text{and} \quad |e, 1\rangle \leftrightarrow |11\rangle. \]

The reader can check that the quantum circuit of figure 8.6 acts on the computational basis as follows:

\[ |00\rangle \rightarrow |00\rangle, \quad |11\rangle \rightarrow |11\rangle, \]
\[ |01\rangle \rightarrow \cos \left( \frac{\Omega_0 t}{2} \right) |01\rangle - \sin \left( \frac{\Omega_0 t}{2} \right) |10\rangle, \]
\[ |10\rangle \rightarrow \cos \left( \frac{\Omega_0 t}{2} \right) |10\rangle + \sin \left( \frac{\Omega_0 t}{2} \right) |01\rangle, \]
that is the same evolution obtained with the Jaynes-Cummings Hamiltonian of Eq. (8.28), except for what concerns the state \( |11\rangle = |e, 1\rangle \), since, in this case, we have:

\[ \exp \left( -i \frac{\hat{H}_\text{int}}{\hbar} t \right) |e, 1\rangle = \cos \left( \frac{\Omega_1 t}{2} \right) |e, 1\rangle + \sin \left( \frac{\Omega_1 t}{2} \right) |g, 2\rangle. \]
As we have seen in the previous section, $\hat{H}_{\text{int}}$ couples the states $|e, 1\rangle$ and $|g, 2\rangle$, but $|g, 2\rangle$ does not belong to the computational space spanned by the two qubits.

In order to solve this problem, we should modify the evolution as follows:

$$\exp \left( -i \frac{\hat{H}_{\text{int}}}{\hbar} t \right) \rightarrow \exp \left( -i \frac{\hat{H}_{\text{int}}}{\hbar} t \right) \left[ \hat{P}_q - |e, 1\rangle \langle e, 1| + |e, 1\rangle \langle e, 1|, \right]$$

where we introduced the projector operator $\hat{P}_q = \sum_{A=g,e} \sum_{F=0,1} |A, F\rangle \langle A, F|$, which projects the state onto the 4-dimensional space spanned by the 2-qubit computational basis.

We close this section showing how we can map an atomic superposition state $|\psi_A\rangle = c_e|e\rangle + c_g|g\rangle$ onto the cavity field state. To this aim it is enough to prepare the field in the vacuum state and then apply a $\pi$-pulse, namely (note that, here, 0 and 1 represent the number of photons):

$$(c_e|e\rangle + c_g|g\rangle) |0\rangle \xrightarrow{\text{\pi-pulse}} |g\rangle (c_e|1\rangle + c_g|0\rangle),$$

i.e., the atom is left in the ground state while the cavity is a superposition state with the same complex amplitudes of the input atomic state. On the other hand, when we try to map the state $|\psi_A\rangle = c_1|1\rangle + c_0|0\rangle$ of the field onto an atomic state, we obtain:

$$|g\rangle (c_1|1\rangle + c_0|0\rangle) \xrightarrow{\text{\pi-pulse}} (-c_1|e\rangle + c_0|g\rangle)|0\rangle,$$

i.e., we have a phase appearing in front of $|e\rangle$. It is worth noting that the field considered throughout this chapter is inside a cavity and, thus, is not directly accessible: one should measure the atom after the interaction in order to have some information about the cavity state!

Chapter 9

Superconducting qubits: charge and transmon qubits

In this chapter we explain how it is possible to obtain a two-level system starting from superconducting circuits. In particular we consider the Josephson junction and the SQUID and we focus on the charge qubit and the transmon qubit. We also describe the coupling between a charge qubit and a 1-D transmission line resonator leading to a coupling Hamiltonian similar to that obtained in cavity QED experiments.

9.1 The LC circuit as a harmonic oscillator

We consider a circuit involving an inductor (with inductance $L$) and a capacitor (with capacity $C$). If we indicate with $V$ the voltage at the ends of the capacitor and with $I$ the current flowing in the circuit, the energies stored in the capacitor and in the inductor are:

$$E_C = \frac{1}{2} CV^2 = \frac{Q^2}{2C}, \quad \text{and} \quad E_L = \frac{1}{2} LI^2 = \frac{\Phi^2}{2L},$$

respectively, where $Q = CV$ is the charge of the capacitor and $\Phi = LI$ is the magnetic flux in the inductor. The classical Hamiltonian $H_{cl} = E_C + E_L$ is:

$$H_{cl} = \frac{Q^2}{2C} + \frac{\Phi^2}{2L},$$

$$= \frac{Q^2}{2C} + \frac{1}{2} \omega_0^2 \Phi^2,$$

that is the classical Hamiltonian of a harmonic oscillator with “mass” $C$, momentum $Q$, position $\Phi$ and frequency $\omega_0 = 1/\sqrt{LC}$. 

103
Chapter 9: Superconducting qubits: charge and transmon qubit

9.1.1 Quantization of the LC circuit

The quantization of $H_{cl}$ is achieved by the substitution (see also section 8.2.4):

$$Q \rightarrow \hat{Q} = i \sqrt{\frac{\hbar}{2Z_0}} (\hat{a}^\dagger - \hat{a}), \quad \text{and} \quad \Phi \rightarrow \hat{\Phi} = \sqrt{\frac{\hbar Z_0}{2}} (\hat{a}^\dagger + \hat{a}),$$

where we introduced the impedance $Z_0 = \sqrt{L/C}$ and the annihilation and creation operators $\hat{a}$ and $\hat{a}^\dagger$, respectively, $[\hat{a}, \hat{a}^\dagger] = \mathbb{I}$. Note that $\hat{\Phi}$ and $\hat{Q}$ are conjugated quantum variables, namely:

$$[\hat{\Phi}, \hat{Q}] = i \mathbb{I}. \quad (9.1)$$

As usual, the quantum Hamiltonian reads:

$$\hat{H}_{LC} = \frac{\hbar \omega_0}{2} (\hat{a}^\dagger \hat{a} + \frac{1}{2}), \quad \hat{H}_{LC} |n\rangle = E_n |n\rangle,$$

where $|n\rangle$, $n \in \mathbb{N}$, are the corresponding eigenstates with eigenvalues $E_n = \hbar \omega_0 (n + 1/2)$.

Since the difference between two levels $\Delta E = E_{n+1} - E_n = \hbar \omega_0$ is independent of $n$, we cannot select only two particular levels in order to obtain a qubit. To make the energies of the quantized levels different enough to obtain a two level system, we should introduce some nonlinearity, which leads to a nonlinear oscillator.

9.2 The Josephson junction and the SQUID

A Josephson junction consists of two superconductors connected via a tunneling barrier. It can be described by its critical current $I_c$, which depends on the SC material and the size of the junction, and the gauge invariant phase difference $\varphi$ across the junction. Furthermore, the two Josephson equations:

$$I_J(t) = I_c \sin \varphi(t), \quad (1\text{st Josephson equation}) \quad (9.2)$$
$$\frac{\partial \varphi(t)}{\partial t} = \frac{2\pi \Phi_0}{V}, \quad (2\text{nd Josephson equation}) \quad (9.3)$$

allow to describe the time evolution of the Josephson current $I_J$ and of $\varphi$ as a function of the applied voltage $V$. In Eq. (9.3) we introduced the superconducting flux quantum $\Phi_0 = \hbar / (2e) = 2.07 \times 10^{-15} \text{ Wb}$, where $2e$ is the charge of a Cooper pair. The time derivative of Eq. (9.2) gives:

$$\dot{I}_J = I_c \cos \varphi \frac{\partial \varphi}{\partial t},$$

and, using Eq. (9.3) and since $I = V / L$, we can introduce the following nonlinear inductance:

$$L_J = \frac{1}{\cos \varphi} \frac{\Phi_0}{2\pi I_c}.$$
The energy associated with $L_J$ is obtained as follows:

$$E_{J,L} = \int_0^t d\tau I_J(\tau) V = E_J(1 - \cos \varphi),$$

where:

$$E_J = \frac{\Phi_0 I_c}{2\pi}$$

is the Josephson energy, which is a measure of the coupling across the junction. Since a Josephson junction has also a capacitance $C_J$, we can calculate the corresponding energy:

$$E_{J,C} = \frac{Q^2}{2C_J},$$

where $Q$ is the charge of the junction.

The classical Hamiltonian of the Josephson junction can be written as (we neglect the constant term):

$$H_J = \frac{Q^2}{2C_J} - E_J \cos \varphi. \tag{9.4}$$

Since $Q = (2e)N$, where $N \in (-\infty, +\infty)$ is the excess of Cooper pair in the Junction, $N = N_1 - N_2$, where $N_1$ and $N_2$ represent the numbers of Cooper pairs present at each side of the junction, we can define the capacitive energy $E_c = \frac{e^2}{(2C_J)}$, and Eq. (9.4) becomes:

$$H_J = 4E_c N^2 - E_J \cos \varphi. \tag{9.5}$$

Instead of a single Josephson junction we can consider two Josephson junctions connected in parallel on a superconducting loop: this system is called SQUID (Superconducting QUantum Interference Device). If the inductance of the loop can be neglected, then the corresponding Hamiltonian is the same as in Eq. (9.5), but now:

$$C_J \rightarrow 2C_J^{(s)}, \quad E_J \rightarrow E_J^{(s)}(\Phi_c) = 2E_J^{(s)} \cos \left(\frac{\Phi_c}{\Phi_0}\right),$$

where $C_J^{(s)}$ and $E_J^{(s)}$ are the single Josephson junction capacitance and energy, respectively, and $\Phi_c$ is the (eventual) external flux: changing $\Phi_c$ one can modify $E_J$. 

**Figure 9.1:** A SQUID embedded in a circuit with a gate voltage $V_g$. 

The Josephson junction and the SQUID
From now on we assume that our system is a SQUID embedded in a circuit and a gate voltage \( V_g \) is applied through a capacitance \( C_g \), as shown in Fig. 9.1. The presence of \( V_g \) simply shifts \( N \) in Eq. (9.5) by \( N_g = C_g V_g / (2e) \), namely:

\[
H = 4E_c (N - N_g)^2 - E_J \cos \varphi, \tag{9.6}
\]

where, now:

\[
E_c = \frac{e^2}{2(C_J + C_g)}, \tag{9.7}
\]

If we associate \( 4E_c N^2 \) with the kinetic energy and \( -E_J \cos \varphi \) with the potential energy, then \( H \) represents the Hamiltonian of a nonlinear oscillator, where the conjugated variables are \( N \) (corresponding to the momentum) and \( \varphi \) (corresponding to the position).

### 9.2.1 Quantization of the Josephson junction and SQUID Hamiltonians

We can now obtain the quantum analogue of the Hamiltonian Eq. (9.6) associating with \( \varphi \) and \( N \) the corresponding quantum operators:

\[
\varphi \rightarrow \hat{\varphi}, \quad N \rightarrow \hat{N},
\]

and the quantum Hamiltonian reads:

\[
\hat{H} = 4E_c (\hat{N} - N_g)^2 - E_J \cos \hat{\varphi}. \tag{9.8}
\]

It is worth noting that \( \hat{N} \) is the operator associated with the excess of Cooper pairs \( N \), where \( N \in (-\infty, +\infty) \), and does not correspond to the number operator of the quantum harmonic oscillator, as the one considered for the electromagnetic field in section 8.2.4. We can write the relation between \( \hat{\varphi} \) and \( \hat{N} \) as:

\[
e^{i\hat{\varphi}} \hat{N} e^{-i\hat{\varphi}} = \hat{N} - \hat{1}.
\]

However, since \( \hat{\varphi} \) and \( \hat{N} \) are conjugated variables, being \( [\hat{\varphi}, \hat{N}] = i\hat{1} \), in the basis of the eigenstates of \( \hat{\varphi} \), we have the following association:

\[
\hat{\varphi} \rightarrow \varphi, \quad \text{and} \quad \hat{N} \rightarrow -i \frac{\partial}{\partial \varphi},
\]

and the Hamiltonian rewrites:

\[
\hat{H} = 4E_c \left( -i \frac{\partial}{\partial \varphi} - N_g \right)^2 - E_J \cos \varphi. \tag{9.9}
\]

The solutions of the differential equation \( \hat{H} \psi_m(\varphi) = E_m \psi_m(\varphi) \) are given in terms of the Floquet-type solutions \( \text{me}_m(q, x) \) as follows:

\[
\psi_m(\varphi) = \frac{1}{\sqrt{2}} \text{me}_m(\varphi) \left( - \frac{E_J}{2E_c} \frac{\varphi}{2} \right),
\]
9.2 The Josephson junction and the SQUID

Figure 9.2: $E_m$ as a function of $N_g$ (in each plot, from bottom to top $m = 0, 1, 2$ and 3) normalized with respect to $E_{01} \equiv \min_{N_g}(E_1 - E_0)$ for different values of the ratio $E_J/E_c$. (Top left) $E_J/E_c = 1.0$; (top right) $E_J/E_c = 5.0$; (bottom left) $E_J/E_c = 10.0$; (bottom right) $E_J/E_c = 50.0$. The zero point of energy is chosen as the bottom of the $m = 0$ level.

with:
\[
f(m, N_g) = \sum_{k=\pm 1} \left[ \text{int}(2N_g + k/2) \mod 2 \right] \\
\times \left\{ \text{int}(N_g) - k(-1)^m[(m + 1) \div 2 + m \mod 2] \right\},
\]
where \(\text{int}(x)\) rounds to the integer closest to \(x\), \(x \mod y\) denotes the usual modulo operation, and \(x \div y\) gives the integer quotient of \(x\) and \(y\). The corresponding eigenvalues are:
\[
E_m = E_c a_{-2[N_g-f(m,N_g)]} \left( \frac{E_J}{2E_c} \right),
\]
where \(a_q(q)\) denotes Mathieu’s characteristic value. In Fig. 9.2 we report the behavior of $E_m$, $m = 0, 1, 2$, and 3, as a function of $N_g$ and normalized with respect to transition $E_{01}$, which is the minimum energy separation between the levels $E_1$ and $E_0$, for different values of the ratio $E_J/E_c$.

As shown in Fig. 9.3 we can identify two regimes: the charge regime ($E_c \gg E_J$) and the transmon regime ($E_c \ll E_J$). In each of these regimes we can define a two level system which can be used as a qubit.
9.3 The charge qubit

In the charge regime, $E_J \ll E_c$, our system can be seen as a Cooper pair box (CPB), that is sketched in Fig. 9.4. It consists in a superconducting electrode (the “island”) in contact with a superconducting reservoir though a tunnel junction (the grey zone in figure, which corresponds to a Josephson junction or to the two junctions of the SQUID) with capacitance $C_J$. Excess Cooper pairs may tunnel onto the island in response to an electric field applied by means of the gate capacitance $C_g$ and voltage $V_g$.

In this case we have a well defined number $N$ of tunneling Cooper pairs and, thus, of excess Cooper pairs, and a strongly fluctuating phase. Therefore we can express the Hamiltonian (9.8) as a function of the eigenstates $|N\rangle$ of $\hat{N}$, that is, $\hat{N}|N\rangle = N|N\rangle$, $N \in \mathbb{Z}$; we have:

$$\hat{H}_{\text{CPB}} = \sum_{N=-\infty}^{+\infty} \left[ 4E_c(N - N_g)^2|N\rangle \langle N| - \frac{1}{2}E_J(|N\rangle \langle N+1| + |N+1\rangle \langle N|) \right], \quad (9.10)$$

where the term $|N\rangle \langle N+1| + |N+1\rangle \langle N|$ describes the tunneling through the junction of a single Cooper pair. It is now clear that $E_J$ represents a measure of the coupling across the junction. It is worth noting that the states:

$$|\phi\rangle = \frac{1}{\sqrt{2\pi}} \sum_{N=-\infty}^{+\infty} \exp(iN\phi)|N\rangle$$
9.3 The charge qubit

\[ N_g = -1 \quad N = 0 \quad N = 1 \]

\[ E_0, E_1, ~\sim E_J \]

Figure 9.5: Left plot: energy levels of the states \(|N\rangle\) without interaction \((E_J = 0)\): note the degeneracy at \(N_g = (1 + 2N)/2\). Right plot: as \(E_J \neq 0\) the degeneracy is broken, and, if \(E_J \ll E_c\), we can identify two levels, \(E_0\) (black) and \(E_1\) (red), whose energy difference at \(N_g = (1 + 2N)/2\) is \(\sim E_J\).

are eigenstates of the operator:

\[ \hat{H}_{\text{tun}} = -\frac{1}{2}E_J \sum_{N=-\infty}^{+\infty} (|N\rangle\langle N+1| + |N+1\rangle\langle N|), \]

and \(\hat{H}_{\text{tun}}|\varphi\rangle = -E_J \cos \varphi |\varphi\rangle\), that is we have the following expansion:

\[ \cos \varphi = \frac{1}{2} \sum_{N=-\infty}^{+\infty} (|N\rangle\langle N+1| + |N+1\rangle\langle N|). \tag{9.11} \]

- Exercise 9.1 Prove Eq. (9.11) by the explicit calculation of the matrix elements of \(\cos \varphi\) in the basis of the eigenstates \(|N\rangle\) of \(\hat{N}\), \(N \in \mathbb{Z}\).

If \(E_J\) is negligible, then \(\hat{H}_{\text{CPB}}\) is just the sum of energies \(4E_c(N - N_g)^2\) of the states \(|N\rangle\) (see the left plot in Fig. 9.5): it is interesting to note that, for a particular choice of \(N_g\), states with different number \(N\) may have the same energy (they are degenerate). In particular we can see that the two states \(|N\rangle\) and \(|N+1\rangle\) are degenerate if \(N_g = (1 + 2N)/2\). As one may expect, the presence of the interaction, though weak but not negligible, breaks the degeneracy (see the right plot Fig. 9.5). In particular, an energy gap appears near degeneracy, which, for fixed \(N_g\), allows us to identify two well defined energy levels whose energy difference is \(E_J\) (see the top left plot in Fig. 9.2). In fact, for a fixed \(N\), and considering \(N_g \approx (1 + 2N)/2\), we can assume that only the two states \(|N\rangle\) and \(|N+1\rangle\) are coupled by the interaction (this can be shown more rigorously by considering the interaction picture and the RWA). The corresponding two-level
Chapter 9: Superconducting qubits: charge and transmon qubit

The Hamiltonian can be written as:

$$\hat{H}_{\text{CPB}}(N_g, N) = 4E_c \left[ (N - N_g)^2 |N\rangle \langle N| + (N + 1 - N_g)^2 |N + 1\rangle \langle N + 1| \right] - \frac{1}{2} E_J (|N\rangle \langle N + 1| + |N + 1\rangle \langle N|),$$

$$= 4E_c \left[ (N - N_g) - \frac{1}{2} \right] \hat{\sigma}^{(N)}_z - \frac{1}{2} E_J \sigma^{(N)}_x + 2E_c \left[ (N - N_g)^2 + (N - N_g + 1)^2 \right],$$

(Eq. 9.12)

where we introduced $\sigma^{(N)}_z = |N\rangle \langle N| - |N+1\rangle \langle N+1|$, $\sigma^{(N)}_x = |N\rangle \langle N+1| + |N+1\rangle \langle N|$. The eigenvalues of $\hat{H}_{\text{CPB}}(N_g, N)$ are:

$$E_{\pm}^{\text{CPB}}(N_g, N) = 2E_c \left[ (N - N_g)^2 + (N - N_g + 1)^2 \right] \pm \frac{1}{2} \sqrt{E_J^2 + 16E_c^2[1 + 2(N - N_g)]^2}.$$

Since at degeneracy $N - N_g = -1/2$, Eq. (9.12) rewrites (we neglect the constant term $E_c$):

$$\hat{H}_{\text{CPB}} \equiv \hat{H}_{\text{CPB}}(1/2, 0) = -\frac{1}{2} E_J \sigma_x,$$

(Eq. 9.14)

where $\sigma_x = |0\rangle \langle 1| - |1\rangle \langle 0|$ and $\sigma_z = |0\rangle \langle 0| + |1\rangle \langle 1|$. Since:

$$\hat{H}_{\text{CPB}} \rightarrow \begin{pmatrix} 0 & -\frac{1}{2} E_J \\ -\frac{1}{2} E_J & 0 \end{pmatrix},$$

it is straightforward to find the two eigenvalues:

$$E_{\pm} = \pm \frac{1}{2} E_J, \quad \text{with} \quad E_+ - E_- = E_J,$$

and the corresponding eigenstates:

$$|e\rangle = \frac{|1\rangle - |0\rangle}{\sqrt{2}}, \quad |g\rangle = \frac{|1\rangle + |0\rangle}{\sqrt{2}},$$

with $\hat{H}_{\text{CPB}}|e\rangle = E_+|e\rangle$ and $\hat{H}_{\text{CPB}}|g\rangle = E_-|g\rangle$. Note that:

$$\hat{\sigma}_x = |g\rangle \langle g| - |e\rangle \langle e|, \quad \text{and} \quad \hat{\sigma}_z = |e\rangle \langle g| + |g\rangle \langle e|,$$

where, as usual, $|e\rangle \rightarrow (1, 0)^T$ and $|g\rangle \rightarrow (0, 1)^T$. In the basis $\{|g\rangle, |e\rangle\}$, the Hamiltonian (9.14) simply reads (we neglect the constant term):

$$\hat{H}_{\text{CPB}} = \hbar \frac{\Omega}{2} \hat{\sigma}_z,$$

with $\Omega = E_J / \hbar$, that is the Hamiltonian of an artificial atom which can be used as a qubit.

As a matter of fact, the charge qubit is very sensible to the fluctuations of $N_g$ and, thus, of the gate voltage $V_g$. This problem can be solved considering the so-called transmon regime.
Figure 9.6: Sketch of a typical configuration to implement circuit QED. A superconducting qubit (a CPB, in yellow) is built inside a 1-D transmission line resonator. The final configuration is such that there is a maximum coupling between the qubit and resonator (the rms voltages reaches the maxima at the center of the conductor, see the red lines).

### 9.4 Charge qubit and capacitive coupling with a 1-D resonator

A 1-D transmission line resonator consists of a full-wave section of superconducting coplanar waveguide. If $L_r$ and $C_r$ are the effective inductance and capacitance of the resonator, respectively, then its characteristic frequency is $\omega_r = 1/\sqrt{L_r C_r}$ (typical values are $\omega_r \sim 10 \text{ GHz}$). The quantum Hamiltonian of the resonator may be written as:

$$\hat{H}_r = \hbar \omega_r \left( \hat{a}^\dagger \hat{a} + \frac{1}{2} \right),$$

where $\hat{a}$ is the annihilation operator, $[\hat{a}, \hat{a}^\dagger] = \mathbb{I}$. The 1-D resonator plays the role of the cavity of a cavity QED experiment.

As depicted in Fig. 9.6, a superconducting qubit (here a CPB) is placed inside the 1-D resonator and it plays the role of the atom of the cavity QED setup. The system CPB+resonator are built in such a way that there is a maximum coupling between the qubit and resonator. As schematically shown in Fig. 9.6, the qubit couples with the mode 2 of the resonator (maxima at the center).

The free Hamiltonian of the system reads:

$$\hat{H}_0 = \hbar \omega_r \left( \hat{a}^\dagger \hat{a} + \frac{1}{2} \right) + 4E_c (\hat{N} - N_g)^2 - E_J \cos \hat{\phi}, \quad (9.15)$$

where the the second and the third terms are the same as in Eq. (9.8).

The coupling between the resonator and the CPB is due to the presence of the quantum contribution to the voltage, which leads to the following substitution in Eq. (9.15):

$$N_g \rightarrow N_g + \hat{N}_r, \quad \text{with} \quad \hat{N}_r = \frac{C_g V_{\text{rms}}}{2e} (\hat{a}^\dagger + \hat{a}),$$

where $V_{\text{rms}} = \sqrt{\hbar \omega_r / (2C_r)}$ is the rms voltage corresponding to the mode 2 of the resonator ($\omega_r \rightarrow \omega_r / 2$) and $C_g$ is the gate voltage. After the substitution we obtain the following Hamiltonian which describes also the coupling through the gate voltage (we neglect the constant
Chapter 9: Superconducting qubits: charge and transmon qubit

112

(\hat{H} = \hbar \omega_r \hat{a}^\dagger \hat{a} + 4E_c \left[ (\hat{N} - N_g) - N_q (\hat{a}^\dagger + \hat{a}) \right]^2 - E_J \cos \phi)

where we neglected the terms proportional to $N_q^2$ (note that $V_{rms} \sim \mu V$).

In the charge regime, $E_c \gg E_J$, and, as shown in section 9.3, we can expand the Hamiltonian in the eigenstates $|N\rangle$ of $\hat{N}$. For the sake of simplicity, we consider only the two states $|0\rangle$ and $|1\rangle$. By introducing $\sigma_z = \hat{a}^\dagger \hat{a}$, we have the following identities:

$$\hat{N} = \frac{1}{2} (\hat{1} - \sigma_z) - N_g,$$

$$\left(\hat{N} - N_g\right)^2 = \left(N_g^2 - N_g + \frac{1}{2}\right) - (1 - 2N_g)\sigma_z,$$

$$\left(\hat{a}^\dagger + \hat{a}\right) \left(\hat{N} - N_g\right) = \frac{1}{2} (\hat{a}^\dagger + \hat{a}) \left[ (1 - 2N_g)\hat{1} - \sigma_z \right].$$

If we now use the basis $\{ |e\rangle, |g\rangle \}$ introduced in section 9.3, we have:

$$\sigma_z = \sigma_x = \sigma_+ + \sigma_-,$$

where $\sigma_+ = |e\rangle \langle g|$ and $\sigma_- = |g\rangle \langle e|$; finally we obtain (at the degeneracy point $N_g = \frac{1}{2}$):

$$\hat{H} = \hbar \omega_r \hat{a}^\dagger \hat{a} + \hbar \frac{\Omega}{2} \sigma_z + 4E_c N_q (\hat{a}^\dagger + \hat{a}) (\sigma_+ + \sigma_-),$$

where $\Omega = E_J / \hbar$ and the last term corresponds to the interaction between the artificial atom and the resonator, which is the same interaction addressed in section 8.2.5.

Indeed, it is also possible to couple the transmon qubit with the 1-D resonator. However, the theoretical description of the interaction requires advanced methods of quantum optics and it is left to the interested readers.

9.5 The transmon qubit

Let us focus the attention on Fig. 9.2: as the ratio $E_J / E_c$ increases, the energy levels $E_m$ can be approximated by the oscillating functions:

$$E_m(N_g) \approx E_m(N_g = 1/4) + \frac{\epsilon_m}{2} \cos(2\pi N_g),$$

where:

$$\epsilon_m \approx (-1)^m E_c \frac{2^{4m+5}}{m!} \sqrt{\frac{2}{\pi}} \left( \frac{E_J}{2E_c} \right)^{\frac{m+3}{4}} e^{-\frac{E_J}{8E_c}}.$$

Therefore, in the limit $E_J \gg E_c$ they become almost independent of $N_g$ (see the bottom right plot of Fig. 9.2), and we reach the transmon regime, where “transmon” refers to “transmission
9.5 The transmon qubit

The transmon qubit: a SQUID shunted by a large capacitance $C_B$, that reduces the fluctuations of the gate voltage by reducing $E_c$. This regime is achieved by using the same configuration of the charge qubit (a dc SQUID coupled to a gate voltage $V_g$ via the gate capacitance $C_g$) but now the SQUID is shunted by a large capacitance $C_B$, as depicted in Fig. 9.7. Since for this system:

$$E_c = \frac{\epsilon^2}{2(C_J + C_g + C_B)},$$

by increasing $C_B$ it is possible to decrease $E_c$ in order to obtain the regime $E_c \ll E_f$. In this way the fluctuations of the gate voltage are also reduced.

Since $E_f \gg E_c$, we can expand up to the 4-th order the $\cos \phi$ in Eq. (9.8), obtaining (since the energy levels are independent of $N_g$, this quantity does not appear explicitly):

$$\hat{H}_{\text{tr}} = 4E_c \hat{N}^2 + \frac{1}{2} E_f \phi^2 - \frac{1}{24} E_f \phi^4$$

Equation (9.16) represents the Hamiltonian of a nonlinear oscillator, therefore we can introduce the bosonic field annihilation, $\hat{b}$ and creation, $\hat{b}^\dagger$, operators, respectively, with $[\hat{b}, \hat{b}^\dagger] = \hat{1}$, and put:

$$\phi = \left(\frac{2E_c}{E_f}\right)^{\frac{1}{4}} \left(\hat{b}^\dagger + \hat{b}\right) = 2 \sqrt{\frac{E_c}{h\omega_p}} \left(\hat{b}^\dagger + \hat{b}\right),$$

$$\hat{N} = i \left(\frac{E_f}{32E_c}\right)^{\frac{1}{4}} \left(\hat{b}^\dagger - \hat{b}\right) = i \sqrt{\frac{h\omega_p}{E_c}} \left(\hat{b}^\dagger - \hat{b}\right),$$

where we introduced the Josephson plasma frequency:

$$\omega_p = \sqrt{\frac{8E_f E_c}{h}}.$$
It is easy to show that $[\hat{\phi}, \hat{N}] = i\hbar$ and that Eq. (9.16) becomes:

$$\hat{H}_{\text{Tr}} = \hbar \omega_p \left( \hat{b}^\dagger \hat{b} + \frac{1}{2} \right) - \frac{1}{12} E_c \left( \hat{b}^\dagger + \hat{b} \right)^4,$$

(9.17)

and $\hbar \omega_p = \sqrt{8E_J/E_c}$. Since $E_c \ll E_J$, in order to calculate the eigenvalues of Eq. (9.17) we can apply the first order perturbation theory. The unperturbed eigenvalues of $\hat{H}_{\text{Tr}}$ are:

$$E_n^{(0)} = \hbar \omega_p \left( n + \frac{1}{2} \right),$$

where $\hat{H}_0|n\rangle = E_n^{(0)}|n\rangle$. The first order correction to $E_n^{(0)}$ is given by:

$$E_n^{(1)} = -\langle n | \left[ \frac{1}{12} E_c \left( \hat{b}^\dagger + \hat{b} \right)^4 \right] |n\rangle$$

$$= -\frac{1}{12} E_c \langle n | \left[ 12 \hat{b}^\dagger \hat{b}^2 + 6 (\hat{b}^\dagger)^2 \hat{b}^2 + 3 + \text{(terms s.t. } \langle n | \cdots | n \rangle = 0) \right] |n\rangle$$

$$= -E_c n - \frac{1}{2} E_c n(n-1) - \frac{1}{4} E_c.$$

Neglecting the constant term, the perturbed energy levels are:

$$E_n = \left( \sqrt{8E_J/E_c} - E_c \right) n - \frac{1}{2} E_c n(n-1).$$

It is worth noting that, due to the nonlinearity, the difference between adjacent levels is now dependent on $n$, namely:

$$\Delta E_{n,n+1} = E_{n+1} - E_n = \left( \sqrt{8E_J/E_c} - E_c \right) - E_c n.$$

In particular, we have:

$$\Delta E_{0,1} = \sqrt{8E_J/E_c} - E_c,$$

$$\Delta E_{1,2} = \Delta E_{0,1} - E_c.$$

Since typical values of the involved quantities are $E_J/\hbar \approx 2 \text{ GHz}$ and $E_c/\hbar \approx 400 \text{ MHz}$ (usually, $C_J \approx 10^{-12} \text{ F}$), it is possible to experimentally select only the transition between the levels $E_0$ and $E_1$, thus obtaining the so-called transmon qubit.

It is worth noting that the gain in charge-noise insensitivity as $E_J/E_c$ increases, leads also to a loss in anharmonicity. In order to reduce a many-level system to a qubit, that is a system with two well-defined levels, a sufficient anharmonicity is required. Form the experimental point of view this sets a lower bound on the duration of control pulses to implement the quantum logic gates. However it is possible to show that the energy ratio should satisfy $20 \lesssim E_J/E_c \ll 5 \cdot 10^4$, opening up a large range with exponentially decreased sensitivity to charge noise and yet sufficiently large anharmonicity for qubit operations. The interested reader can find further details in the references cited in the Bibliography.
